b. Large amount of secretion, most of which is eosine staining in stained sections.

3. Advanced Degeneration.

Shown by

a. Dense staining of most of the secretion.

b. More or less complete exfoliation of the parenchyma.

This grouping was made on the following working hypothesis, which was merely an elaboration of Möbius's theory: First, the symptoms of Graves's disease are associated with increased absorption of an increased secretion of the thyreoid gland. Second, the more functionally active parenchyma cells in the gland the larger the amount of its secretion. Third, the more fluid the secretion of the gland the more readily will it be absorbed. Fourth, the cells partly disintegrated found inbedded in the secretion in alveoli with partially or wholly naked walls are mostly if not entirely desquamated epithelial cells. Fifth, the increased concentration of the stained secretion by the absorption of its more fluid constituents and by the desquamation of the alveolar epithelium must tend to reduce absorption from the gland as a whole. Sixth, the dense gelatinous well stainable secretion, the so called "colloid," in any thyreoid gland is not, strictly speaking, a normal product, but the complement of the absorbed portion. Seventh, when dense colloid material fills the alveoli of the thyreoid gland it must be regarded as evidence, not of present secretion, but as indicative of degeneration. Eighth, when, therefore, we measure either histologically or chemically the relative colloid (globulin) contents of the gland, we should bear in mind that we are probably not determining factors which have actually caused the symptoms, but only their associated phenomena.

On such a basis, a very simple hypothesis of the development of Graves's disease might be formulated as follows: 1, Following a metabolic, chemical, or extraorganismal irritant, thyreoid parenchyma proliferates, but is functionless and degenerate. 2, This process may be primarily simple adenoma or adenopapilloma. 3, Either process may start in a gland not previously enlarged by retained secretion, or in one which is already distended with nonabsorbed secretion. 4, The severity of the symptoms depend upon (a) the amount of absorbable secretion, and (b) the patient's ability to neutralize the

The author said that, while their cases were too-

few from which to draw positive conclusions, yet. so far as they went, one would seem to be warranted in making the following tentative statement from the clinical standpoint: I. Very early acute cases showed pathologically hyperæmia and cellular hyperplasia, if not throughout the gland, at least in much of it, provided, of course, the more enlarged lobe had been removed. 2. Later acute, moderate, severe, and very severe cases showed greater parenchyma increase and in many instances evidence of increased absorbable secretion. Speaking broadly, the parenchyma increase was in direct proportion to the intensity of the symptoms. The relatively few variations from this rule might be accounted for by the varying resisting power of different individuals. Where relatively small amounts of absorbable secretion were found in alveoli whose walls were crowded with functionally active cells, we must assume that the secretion had already been absorbed. In fact, it would seem a necessary conclusion that, in any gland with a given amount of secreting parenchyma, the less secretion found in its alveoli at any given moment the greater the amount that had been absorbed. In regard to the secretion, both the histologist and the chemist were measuring only the complement of that portion which had been absorbed and which was directly responsible for the symptoms. 3. Cases which clinically were showing any remission of toxic symptoms, showed somewhere within the gland more or less evidence of decreased function in the exfoliation or flattening of parenchyma cells, or of decreased absorption, by the presence of thick, gelatinous, stainable, secretion so called "colloid." 4. Patients who had recovered from their toxic symptoms, and were now suffering principally from long previously acquired heart or nerve lesions, showed exfoliated or flattened, nonsecreting epithelium and large quantities of well stained, thick, gelatinous, nonabsorbable colloid. In this class of cases it would seem as futile to search for previous causative parenchyma increase as to look for diphtheria membrane in the throat of a patient suffering from postdiphtheritic paralysis. As for the thick, gelatinous colloid itself, it was difficult to conceive of its ever being absorbable, but even in the thyreoids of healthy individuals it was but the retained complement-degenerated probably-of the absorbed portion of the secretion. Its presence in large quantities in any thyreoid would seem to bear a similar relation to secretion and excretion by the gland as the retained urine in a hydronephrosis did to secretion and excretion by the urinary apparatus. 5. The recently developed, very mild, or the moderately mild cases of long standing were almost always pathologically adenomata in which, while there was some total parenchyma increase by the multiplication of alveoli, there was not greatly increased functional power of the individual parenchyma cells. Goitre of the adenoma type apparently passed through the same changes of hypertrophy and degeneration as the cof the adenopapilloma type: 6. Simple goitres hould be regarded as multiple retention cysts filled with nonabsorbable secretion, cell detritus, etc.

The Surgical Aspects of Exophthalmic Goître. —Dr. WILLIAM S. HALSTED, of Baltimore, said that surgeons were interested in this disease not only

from the surgical aspect, but from the ætiological and pathological aspects as well. Dr. Wilson's demonstration had interested him very much, the pictures showing familiar conditions met with in this disease, but seldom had the opportunity been given to see such beautiful reproductions of sections. It was interesting to observe that the histological history often gave evidence of the clinical history, and in a few instances indicated a grave condition. He reported some experiments made on dogs, producing artificially hypertrophy of the thyreoid. Excising a portion of one lobe of the thyreoid in a dog produced an hypertrophy of the remainder of the gland and of the accessory thyreoids. He gave a blackboard demonstration of what took place in the dog's gland after such a procedure. The dog might present the typical gland of exophthalmic goitre, but with no symptoms whatever of the disease. He agreed practically to all that Dr. Wilson had stated in his paper.

Without entering into an elaborate classification of this disease, he said that a patient might present himself with quite a large paranchymatous goitre which did not offer the gross lobulations that occurred in the colloid goitre. There might be slight exophthalmic symptoms, without exophthalmos; and, again, there might be nervousness, tachycardia, and a large thyreoid. Although this was not an ordinary colloid goitre, at the same time the patients would state that certain symptoms occurred with the appearance of the goitre. In such a case one could not say that it was a simple case of exophthalmic goitre. Such a condition was not what was generally known as Basedow's disease.

The operation for exophthalmic goitre might be a partial one, such as ligation of the arteries, or the removal of portion of the gland; or one might do a lobectomy. In doing the latter operation one should be very careful not to injure the parathyreoids or to interrupt the circulation. The operation should be as bloodless as possible. One should be careful not to injure the recurrent laryngeal nerve; this nerve was injured more often than surgeons would admit. Dr. Halsted made it a point to look for this nerve after every operation upon the thyreoid gland. Once he found it caught in the ligature, and to-day he used catgut ligatures, because if it was once caught, it would be released when the ligature was absorbed, and so restored in all probability to function. He also made it a point to see that the circulation in the parathyreoids was not cut off.

Transplantation of the parathyreoids could now be done, as had been proved experimentally. But it seemed to him that, to be successful, they first should create a need for parathyreoid tissue. As a result of the work done in Baltimore he felt certain that they were justified in returning parathyreoids in the same human being; but whether they were justified in asking another to give up his thyreoid for such a purpose was open to question. It was interesting to recall the fact that last winter a man presented himself for the removal of a lymphangeioma of the neck, and who was willing to give up his parathyreoids. Upon operation, they found. to their keen disappointment, that no parathyreoids yers to be found. Never before in human beings or animals had they failed to find the parathyreoids.

He said that if they included Basedow's goitre, adenoma, and cysts with symptoms of the disease, they probably had had 170 cases of exophthalmic goître. Until this last winter they had had but one death as a result of the operation. In all, they had had only three or four perfect cures, although they had given much relief in a large number of the

Some Considerations of Exophthalmic Goître from a Medical Standpoint.-Dr. ALFRED STEN-GEL, of Philadelphia, read this paper. (See page 577.)

Retters to the Editors.

SUNLIGHT AND TUBERCULOUS DISEASE

NEW YORK, September 19, 1908.

To the Editors:

I did not intend that my contribution on The Explanation of Seeming Paradoxes in Modern Phthisiotherapy, which you were good enough to publish in your last issue (September 12th), should lead to any controversy. I thought I had confined myself to facts, stating the experience of others and my own. I concluded my communication with the glad admission that all of us would be willing to learn from Dr. Woodruff's further studies.

To my regret, I see that Major Woodruff, in his article entitled The Dangers of Excessive Sunlight in Tuberculosis, has not confined himself to facts, but indulged in fancies and personalities. May I first say a word in defense of Dr. Vincent Y. Bowditch, of Boston, whom Dr. Woodruff accuses of partiality because he could not accept the major's preliminary Report on Sunlight for his section of the Tuberculosis Congress? When Dr. Woodruff told me of Dr. Bowditch's decision, the latter had not yet any knowledge of the subject of my paper. Furthermore, all who know Dr. Bowditch will agree with me that he is too conscientious and scientific a man to refuse any communication for which there was room on the programme, even should his very best friend or the most distinguished colleague of the board of directors of the national association hold a different opinion from that expressed by the author desiring to be heard.

Dr. Woodruff places me in a peculiar light by making the statement that he had not said to me that "about one hundred per cent. of the white soldiers who contract tuberculosis in the Philippines die from this disease," but that all cases in white people in the tropics promptly perish unless they are

It is possible that I may have misunderstood him, presuming that, being a military surgeon, he referred to soldiers alone. But I fail to see the difference between "one hundred per cent." and "all cases in white people," since most of our soldiers are white people, and he admits having stated that "all white people in the tropics contracting tuberculosis promptly perish unless they are sent home.

I have given in my paper above referred to the full names and addresses of all the authorities who kindly expressed their opinions on the subject of sunlight and solar therapy in tuberculosis. Dr.

Woodruff contents himself by saying that a prominent physician of Philadelphia expresses an opinion in accord with what Dr. Woodruff pleases to call the "modern view" that "sunshine is less impor-tant," etc. When one wishes to have his views endorsed by an authority, it would seem to me that it would be better to name this authority. There are many prominent physicians in Philadelphia, and it is hard to surmise whom Dr. Woodruff means.

The major quotes Dr. Sanford Hascom's table, according to which granite cutters have the highest percentage of mortality from tuberculosis, namely, 38.73, printers have 25.44 per cent., barbers 22.61, bookkeepers 18.30, moulders 17.48, and miners the lowest percentage, 2.94. Hotel proprietors have 5.44, city firemen 6.66, master mariners and pilots 6.97, railway trainmen 7.86, and farmers 8.42. I fail to see that these statistics bear out Dr. Woodruff's argument. He says: "This latest table is so important that it is quoted in full to show that light or darkness might have opposite effects from what we now believe. . . . It is remarkable that those that have the most light suffer most and those that have the least have the best record.

Granite cutters do not always work in sunlight. They often work under sheds. Perhaps the majority of printers work at night (particularly those engaged in printing newspapers). Barbers always work indoors and very often, as, for example, in our modern hotels, in badly or artificially lighted basements. It has been demonstrated by post mortem examinations that the high mortality from tuberculosis in granite cutters and printers is due to the inhalation of relatively large amounts of inorganic irritating dust (stone and lead). The remarkably low mortality of miners from tuberculosis in Dr. Hascom's statistical table may be explained by an unusually well ventilated mine where the miners, belonging to the East Summerville branch of the Royal Arcanum, are employed. It must also be remembered that miners' phthisis is not nearly so fatal as tuberculosis pulmonum.

The low mortality of hotel proprietors may well be accounted for, because they live well and usually do not have to work very hard. City firemen, master mariners, pilots, railway trainmen, and farmers are, perhaps, as much benefited by the rays of the sun as any class of workers, and this doubtless is one of the principal reasons for their low mor-

tality from tuberculosis.

No one has ever doubted that excessive sunlight is injurious, as perhaps all excesses are. The object of my paper was not to express a disbelief in the dangers of excessive sunlight, but to refute the major's wholesale condemnation of sunlight as a therapeutic factor and his designating it as a cause of tuberculosis, and to show that his views regarding the greater susceptibility of blondes to tuberculosis and their lesser chances of cure as compared with brunettes had no statistical or scientific basis.

Lastly, Dr. Woodruff in his concluding paragraph refers to Germany, the country of my birth, as my "dark native land," What the place of birth of an American physician, for such I proudly call myself, has to do with his opinions on any medical subject I fail to see. Why Dr. Woodruff should call Germany dark is still a greater mystery to me for

surely a country which has given to the world within one generation an Esmarch, a Brehmer, a Robert Koch, a Röntgen, and a Behring can hardly be called dark regarding medical science. In Germany, my native land, in the United States, the land of my choice and my adopted fatherland, in England, in France, and everywhere, earnest scientists and physicians are imbued with only one desire -to arrive at the truth. Their motto was given to them by a man trained as a physician, a German by birth, it is true, but a poet of the world. It was he, the immortal Goethe, who, on his deathbed, gave to the world as his last message the significant words, "More light! More light!" S. A. KNOPF.

Book Antices.

[We publish full lists of books received, but we acknowledge no obligation to review them all. Nevertheless, so far as space permits, we review those in which we think our readers are likely to be interested.]

The Principles of Pathology. By J. George Adami, M. A., M. D., LL. D., F. R. S., Professor of Pathology in McGill University and Pathologist to the Royal Victoria Hospital, Montreal; late Fellow of Jesus College, Cambridge, England. Volume I, General Pathology. With 322 Engravings and 16 Plates. Philadelphia and New York: Lea & Febiger, 1908. Pp. xvi-17 to 948.

This is one of the profoundest books that have appeared in medicine, in any language, for many a year. It may well be called a philosophy of pathology, with-almost for the first time in our literature—an adequate dash of embryology, that rock on which medicine ought to be largely founded. If the average reader finds much of it hard to understand let him not blame the learned author, for Dr. Adami's diction is beyond criticism in the matter of clearness; let him rather impute his difficulty to the intricacy of many of the subjects handled, and study his way to an appreciation of the great Montreal pathologist's teaching.

Dr. Adami's own convictions, always substantially based, rule in the text, as they ought to do, but he presents the views of others fairly, and he criticises, if criticise he must, with that courtly courtesy for which he is noted. He cites other men's observations and opinions freely - with wonderful comprehensiveness, we may say, when we reflect upon the great loss that he sustained in the destruction of his private library by the fire which not long ago afflicted McGill. In the preface he says pathetically, but without the emotional display for which he might well have been pardoned: manuscript had been completed, and all save a few chapters sent to my publishers, when, in April, 1907, the greater part of the Medical Building at the McGill University was burned to the ground, and with it my library, the chapters in question, and the illustrations I had made or gradually collected over many years for the purposes of the book. It has been impossible to reproduce most of these illustrations, and I have had to fall back upon illustrations from many sources." With characteristic modesty he adds: "I am very far from uncertain as to whether the work has not greatly gained from the greater diagrammatic clearness of the selected illustrations." Here we cannot agree with him, for we think his immercus schemata are more incomi uis

and clearer than those of any other medical author since the late Dr. John C. Dalton. At the same time we feel sure that all Dr. Adami's friends and their name is legion-bewail his grievous loss.

Though this first volume is devoted to general pathology, there are to be found here and there interesting remarks on points in special pathology. Among the sections which the practitioner of medicine will perhaps find most attractive are those on inheritance and allied subjects, on marriages of consanguines, on placental disease and its influence upon the fœtus, on monstrosities and malformations, on the exogenous causes of disease, on the endogenous intoxications, on the pathogeny of puerperal eclampsia, on bacteria and inflammation, on Ehrlich's side chain theory, on opsonic practice, on the nature of Hodgkin's disease, and on Beard's proposed treatment of cancer. It would be a mistake, however, for the reader to neglect any part of the volume; it deserves careful study in its entirety. It is to be hoped that the second volume will be issued before long.

Seventh Annual Report of the Metropolitan Water and Sewerage Board, for the year 1907.

This district in Massachusetts includes Boston, eight other cities, and ten towns, and has an area of 171.7 square miles and a population of 980,900. The condition of the various dams, reservoirs, filter beds, water works, and sewerage works is described. The daily per capita consumption was 133.8 gallons, an increase over the preceding year. A large amount of this increase was waste, due to bad plumbing, leaks, and the custom of allowing the water to run in winter to prevent its freezing in the pipes; the latter waste was enormous, amounting in the coldest week in the year to a daily average of twenty-five per cent. greater, over thirty million gallons more, than the daily average consumption for the entire year. Wherever meters were installed there was a marked decrease in unnecessary consumption; in one town the latter was reduced to almost one third of the amount used before meters were introduced. The work is well illustrated and maintains the high standard of reports from Massachusetts.

BOOKS, PAMPHLETS, ETC., RECEIVED.

Public Health and Marine Hospital Service:

Official list of changes of stations and duties of commissioned and other officers of the United States Public Health and Marine Hospital Service for the seven days ending September 16, 1908

CLARK, T. A., Passed Assistant Surgeon. Granted two days leave of absence from September 15, 1908.

FOSTER, M. H., Passed Assistant Surgeon. Granted twenty-one days' leave of absence from September 16, 1908.

HOBDY, W. C., Passed Assistant Surgeon. Granted fourteen days' leave of absence from September 16, 1908; directed to proceed to Mare Island Naval Station on special temporary duty.

Keiller, William, Acting Assistant Surgeon. Leave of absence for twenty-three days from August 13, 1908.

MEGAW, H., Pharmacist. Directed to proceed to Washington, D. C., for temporary duty.

OSBORN, J. L., Pharmacist. Assigned to station at Chelsea,
Boston, Mass. amended to read seven days from August 13,

Schereschewsky, J. W., Passed Assistant Surgeon. Granted thirty days' extension of leave of absence from September 17, 1908.

STIMSON, A. M., Passed Assistant Surgeon. Directed to proceed to Los Angeles, Cal., upon special temporary

WALKLEY, W. S., Acting Assistant Surgeon. Granted cleven days' leave of absence from September 12, 1908. WASDIN, E., Surgeon. Granted fifteen days' extension of leave of absence.

WERTENBAKER, C. P., Surgeon. Detailed to represent the Service at the International Congress on Tuberculosis, September 21 to October 3, 1908.

WHITE, J. H., Surgeon. Granted seven days' leave of absence from September 9, 1908, under paragraph 189, Service Regulations.
Young, G. B., Surgeon. Directed to proceed to Milwaukee,

Wis., upon special temporary duty.

Appointment.

J. L. Osborn appointed a pharmacist of the third class, September 12, 1908

Boards Convened.

Board of medical officers convened to meet at the Marine Hospital, Chicago, Ill., September 18, 1908, for the purpose of making a physical examination of an applicant for the position of Cadet in the Revenue Cutter Service: Surgeon G. B. Young, chairman; Assistant Surgeon C. E. Wood, recorder.

Board of medical officers convened to meet at New Orleans, La., September 17, 1908, for the purpose of making reexamination of alicns: Passed Assistant Surgeon H. W. Wickes, chairman; Assistant Surgeon C. M. Fauntleroy, and Acting Assistant Surgeon J. T. Scott, recorder.

Army Intelligence:

Official list of changes in the stations and duties of officers in the Medical Corps of the United States Army for the week ending September 19, 1908:

BAILEY, EDWARD, Medical Reserve Corps. Ordered to ac-

tive duty in the service of the United States, and assigned to duty at Fort George Wright, Washington.

BAILY, H. H., Captain. Appointed a member of a board of officers to meet at the Army Dispensary, Washington, September 22, 1908, and on such other dates as may be necessary for the purpose of conducting the physical examinations prescribed in G. O. 79, War Department, May 14, 1908, on such field officers as may

partment, May 14, 1908, on such field officers as may be ordered before it.

Bruns, E. H., First Lieutenant. Relieved from further duty at Fort Monroe, Va., and ordered to proceed to Fort Bayard, N. M., and report in person to the commanding officer of the General Hospital, for duty.

CULLER, R. M., Captain. Relieved from duty at Fort Monroe, Va., and ordered to Fort Ontario, N. Y., for duty, instead of Fort Logan H. Roots, Ark., as heretofore ordered

CUTLIFFE, W. O., Medical Reserve Corps. Ordered to
Fort McIntosh, Tex., for duty.

Dade, W. H., Medical Reserve Corps. Granted leave of

absence for two months and fifteen days.

Duncan, L. C., Captain. Appointed a member of a board of medical officers to meet at Fort William H. Harrison, Mont., for the examination of such officers of the Medical Reserve Corps as may be brought before it to determine their fitness for retention in service.

FORD, J. H., Captain. Appointed a member of a board of medical officers to meet at Fort William H. Harrison. Mont., for the examination of such officers of the Medical Reserve Corps as may be brought before it to determine their fitness for retention in service.

LLIDAY, C. H., Medical Reserve Corps. Relieved from duty at Fort Sam Houston, Tex., and ordered to Fort

Fremont, S. C., for duty. HALLIDAY, F. A., First Lieutenant. Retired from active

service, September 13, 1908.

Jones, G. B., Medical Reserve Corps. Relieved from duty at Fort George Wright, Washington, and ordered to Fort Benjamin Harrison, Ind.

KILBOURNE, E. D., Captain. Relieved from duty at Fort

Brady, Mich., to take effect at such time as will enable him to comply with order; will proceed to San Francisco, Cal.; take transport sailing for Manila, November 5, 1908; and on arrival, will report to the commanding general, for assignment to duty.

Lynch, Charles, Major. Detailed to act as judge at the third annual contest of the First Aid Corps of the Pennsylvania Coal 'Co. and the Hillside Coal & Iron Co., to be held on Saturday, October 3, 1908, at Inker-

man, near Scranton, Pa.

PED, G. P., Captain. Relieved from duty at Fort Ontario, N. Y., and ordered to Fort Monroe, Va., for duty. Quinton, W. W., Captain. Granted thirty days' sick leave, SCHMITTER, FERDINAND, First Lieutenant. Ordered to Fort Logan H. Roots, Ark., for duty.

SILER, J. F., Captain. Detailed to act as judge at the third annual contest of the First Aid Corps of the Pennsylvania Coal Co. and the Hillside Coal & Iron Co., to be held on Saturday, October 3, 1908, at Inkerman, near

Scranton, Pa. WINTER, F. A., Major. Appointed a member of a board of officers to meet at the Army Dispensary, Washington, September 22, 1908, and on such dates as may be necessary for the purpose of conducting the physical examinations prescribed in G. O. 79. War Department, May 14, 1908, of such field officers as may be ordered

before it. WOODBURY, F. T., Captain. Leave of absence extended fif-

Navy Intelligence:

Official list of changes in the stations and duties of officers of the Medical Corps of the United States Navy for the week ending September 19, 1908:

BISHOP, D. W., Passed Assistant Surgeon. Ordered to duty at the Naval Hospital, New York.

BOGERT, E. S., Surgeon. Detached from the Naval War College, Newport, R. I., and ordered to the Naval Recruiting Station, New York.

DOLLARD, H. L., Assistant Surgeon. Detached from the Rhode Island and ordered to the Albatross.

FORTED T. G. Assistant Surgeon.

FOSTER, T. G., Assistant Surgeon. Detached from the Naval Training Station, Newport, R. I., and ordered to the Naval Hospital, Newport, R. I.

GILTNER, H. A., Assistant Surgeon. Appointed an assistant surgeon, from September 10, 1908.

HENRY, R. B., Assistant Surgeon. Appointed an assistant

surgeon, from September 10, 1908.
Hoen, W. S., Passed Assistant Surgeon. Detached from duty as assistant to the inspector in charge of the third lighthouse district, Tompkinsville, N. Y., and ordered to the Naval Hospital, New York, for treatment. McCormick, A. M. D., Surgeon. Detached from the Naval

Academy, and ordered to the Naval Recruiting Station.

Baltimore, Md.

McMurdo, H. B., Acting Assistant Surgeon, Detached from the Naval Training Station, San Francisco, Cal.,

and ordered to take a course of instruction at the Naval Medical School, Washington, D. C.

MACKENZIE, E. G., Assistant Surgeon. Detached from the Naval Hospital, New York, and ordered to take a course of instruction at the Naval Medical School, Washington, D.

Washington, D. C.
May, H. A., Passed Assistant Surgeon. Detached from the Naval Hospital, Norfolk, Va., and ordered to duty with lighthouse vessels en route to the Pacific Coast.

MARSTEILER, E. H., Surgeon. Transferred to the retired list from September 15, 1908, upon his own application after the completion of thirty years' service, in accordance with a provision of the naval appropriation act of May 13, 1908; detached from the Naval Recruiting Sta tion, Baltimore, Md., September 15th, and ordered

MURPHY, J. A., Surgeon. Ordered to temporary duty on board the Franklin.

OLD, E. H. H., Assistant Surgeon. Ordered to duty at the Naval Hospital, Norfolk, Va., September 15, 1908.
PHELPS, J. H., Assistant Surgeon. Detached from the Naval Hospital, Boston, Mass., and ordered to take a course of instruction at the Naval Medical School, Washington, D. C., October 1st. Reed, E. U., Assistant Surgeon. Detached from the navy

yard, Mare Island, Cal, and ordered to the Naval Training Station, San Francisco, Cal.

STERNE, C. F., Assistant Surgeon. Detached from the Naval Hospital, New York, and ordered to take a course of instruction at the Naval Medical School. Washington, D. C

Wells, H., Medical Director. Detached from the Naval Recruiting Station, New York, and ordered to the navy yard, Portsmouth, N. H., and to additional duty in command of the Naval Hospital at that yard.

WHITESIDE, L. C., Acting Assistant Surgeon. Detached from duty at the Naval Hospital, Newport, R. I., and ordered to take a course of instruction at the Naval Medical School, Washington, D. C.

Births, Marriages, and Beaths.

Born.

NELSON.—In Manila, Philippine Islands, on Monday, July 6th, to Captain Kent Nelson, Medical Corps of the United States Army, and Mrs. Nelson, a daughter.

Married.

KENNEY—FARRANT.—In Norwich, Connecticut, on Tuesday, September 15th, Dr. John W. Kenney, of Northampton, Massachusetts, and Miss Rose C. Farrant.

LOBB-CHARLTON.—At Paoli, Pennsylvania, on Wednesday. September 16th, Dr. Norman H. Lobb, of Devon, Pennsylvania, and Miss Mary Isabel Charlton.

OWENS—SEYMOUR.—In Lakeville, Connecticutt, on Sat-urday, September 12th, Dr. William Dunlop Owens, United States Navy, and Miss Elise Seymour. PRIEST—Dowdy.—In Fort Bayard, New Mexico, on Wednesday, September 9th, Lieutenant Howard Priest, Medical Reserve Corps, United States Army, and Miss

SHRIER—DANZIGER.—In New York, on Tuesday, September 15th, Dr. Albert F. Shrier and Miss Clara E. Danziger.

To no. Konyy 19 Salem, New Jersey on Wednesday, September 16th, Dr. James L. Touhy and Miss Margaret R. Kohan.

Buddeke.—In New York, on Friday, September 11th, Dr. Charles I. Buddeke, aged thirty-four years.

Code.—In New Orleans, Louisiana, on Thursday, September 10th, Dr. James Francis Code, aged thirty-four

LANDON.—In Kansas City, Missouri, on Thursday, September 10th, Dr. Solomon S. Landon, aged thirty-six

LAWRENCE.—In Ballston Spa, New York, on Friday, September 11th, Dr. Eben Seward Lawrence, aged fifty-

MALECK.-In San Francisco, California, on Monday, Sep-

MALECK.—In San Francisco, California, on Monday, September 7th, Dr. Herman F. Maleck, aged fifty-four years.

MAY.—In New Baltimore, Michigan, on Tuesday, September 15th, Dr. Lewis P. May, aged fifty years.

SHERMAN.—In Tyro, Kansas, on Tuesday, September 8th, Dr. L. G. Sherman, aged seventy-three years.

SMITH.—In Lowell, Massachusetts, on Saturday, September 12th, Dr. Hermon J. Smith, aged seventy-one years.

VAN SCOYOC.—In Los Angeles, California, on Wednesday, September oth, Dr. L. G. Van Scoyoc, aged fifty years.

WILKIN.—In South Farmington, Massachusetts, on Saturday, September 12th, Dr. Anna M. Wilkin.

urday, September 12th, Dr. Anna M. Wilkin.

IRREMOVABLE CANCER.*

By William Seaman Bainbridge, Sc. D., M. D., New York,

Surgeon, New York Skin and Cancer Hospital; Secretary, Committee on Scientific Research, New York Skin and Cancer Hospital; Honorary President, First International Congress on Cancer, Heidelberg, Etc.

It has been the custom of the New York Skin and Cancer Hospital for a number of years to hold an annual clinic for the purpose of reviewing certain phases of the cancer problem. On the first of these occasions we gave a brief résumé of the status of the cancer question at that time with reference to occurrence, ætiology, and the different methods of treatment. The following facts were emphasized, and I repeat them now, because three years of added experience and study give us no reason for modifying the statements then made, and because they have a direct bearing upon the subject of irremovable cancer.

1. All cancer begins as a benign growth.

2. There is, therefore, a true precancerous stage, in which removal is a sure means of relief.

3. The disease is absolutely local in its beginning, and if fully extirpated a cure should result.

4. Extension may take place by direct infection of the surrounding tissue, but it is usually through the lymphatics or blood channels.

5. There is a varying degree of malignancy, some growths tending to return more readily than others.

6. The system is poisoned by the production of toxines.

7. General malnutrition, as well as diminished vitality of the noncancerous tissue in the neighborhood of malignant disease, as a rule, tends to increase the rapidity of the local extension and renders more likely the development of metastases.

At the second clinic we discussed the surgical treatment of cancer, giving statistics to prove that in this lies the only means of eradication of the dis-

Last year, at the third clinic, we reviewed in brief the work of the First International Congress on

Cancer at Heidelberg.

We come now to the discussion of that phase of the subject from which we fain would turn away, so pitiful and heartrending are some of the scenes which it entails; but to do so would be cowardice indeed. Unfortunately, through ignorance on their

own part many times, and often through the false hopes instilled into their minds by medical charlatans, patients with cancer are in the irremovable stage when they come under the care of the surgeon. It is then too late to effect a cure, but there is much yet to be done for these individuals in the way of relieving the awful suffering and prolonging life for weeks, months, and even years in comparative comfort. From time to time in the secular press, and occasionally in medical journals, a discussion arises concerning the wisdom and humanity of resorting to euthanasia for those afflicted with incurable disease, particularly incurable cancer. We are not ready to sound the death knell, and to advocate painless death, when the allotted span of life may be passed in relative ease and death result, as is many times the case, from some condition other than the cancer, or, perhaps, from internal cancer secondary to the original disease. In the latter case the patient is often unaware of the fact that he is suffering from cancer, and dies with the comforting thought that at least death from external evidence of a loathsome disease was spared him. The following cases' very well illustrate this point:

Case I.—Mrs. C. J. W., aged fifty-one, private patient, first consulted me January 24, 1907. In March, 1905, she had received a blow on the left breast, and in October of the same year she first noticed a lump the size of an English walnut in the breast. It did not increase in size. The entire mass, with a margin of sound tissue, was removed by another surgeon, December 12, 1905. This was examined microscopically and found to be malignant. The entire breast was removed in January, 1906, but the axilla was not cleared. In November, 1906, a nodule was found in the scar of the previous operation. In January, 1907, she came from a distant State to New York to receive treatment by one of the new methods at present receiving more or less attention. At that time I found recurrent cancer extending well up to the neck on the side of the breast cancer, and the glands in the axilla were involved. The patient not only had the cancerous condition, but was markedly anæmic, the liver was considerably enlarged, and she had a good deal of intestinal and gastric indigestion. On January 31, 1907, I removed all the tissues in the axilla, and the glands in the neck, taking everywhere a margin of healthy tissue. The wound healed by primary union. The patient returned home, free from external cancer, and lived nine months, dying of internal cancer of which she remained ignorant to the last.

Without this radical operation there would undoubtedly have been a rapid breaking down of the cancer, and her remaining days would have been spent in the mental and physical anguish entailed by a broken down and sloughing external cancer.

CASE II.—Mrs. C., consulted me eight years ago. She had cancer of the right breast and axilla, and beginning

¹The cases reported herewith are selected from the large number presented at the clinic.

^{*}Abstract of Fourth Annual Clinical Lecture, delivered at the New York Skin and Cancer Hospital, April 22, 1908.

disseminated spinal sclerosis, with certain paralysis of the lower limbs at no distant date. Her physician had told her that under no circumstances should she submit to operation, as the risk was too great. She was admitted to the Alston Private Hospital, and on May 5, 1900, we removed

Fig. 1.-Epithelioma and lupus erythematosus

all the diseased tissue. The wound healed by primary union, and the patient lived for two years, free from the thing she so much dreaded, though she became paralyzed below the waist.

To have consigned this woman to the horrors of death from or with a broken down cancer, particularly with paralysis an almost certain concomitant, would have been cruel in the extreme. Euthanasia would have been more justifiable on any basis of religion or ethics.

Case III.—Mrs. R., who came from the west to the New York Skin and Cancer Hospital, had been told by several physicians that the cancer in her right breast was too far advanced for anything to be done by operative procedure. I operated upon her in the latter part of 1904, removing, with great difficulty, the entire right breast and clearing completely the axilla. The wound healed promptly primary union, and the patient returned home in fair condition, remaining free from recurrence for a year. A little nodule then appeared in the secar and she returned to this hospital. On October 25, 1905, I removed all the diseased tissue. The patient remained well and strong for a number of months. She then began to have some trouble with the liver, acute pneumonia developed, and she died October 20, 1906, one year after the second operation. There was no local recurrence, and while the patient undoubtedly had cancer of the liver and perhaps of other internal organs, she never knew it.

With a cancer of the breast so far advanced as to be pronounced inoperable, had this not been removed by radical operation, her suffering, both of mind and body, can be easily imagined.

It has been said by some conservatives that our surgery in cases of advanced cancer is too radical—in the face of the unspeakable suffering of many of these patients it may be truly said, it were

"Better, almost, be at work in sin.

Than in brute inaction browse and sleep."
The doctor, and those who make up the immediate world of the victim of advanced cancer, are all too prone to say, "Oh, it is incurable—nothing can

be done." They fail to realize that the patient is a human being who, while suffering from cancer, it is true, may at the same time be the subject of any of the other ills to which human flesh is heir; they consider such an individual, rather, as a "cancer case," for whom little, if anything, can be done. In consequence of this attitude the cancer, rather than the patient, is treated, if, indeed, anything at all is done. The gloom of the doctor is reflected back upon the patient, and it is no wonder that the cry for something to end it all is often heard. If we can, by radical surgery or otherwise, throw into the darkness even one faint ray of light, surely it is the part of human kindness to do so!

We have classified the cases of irremovable cancer under the following heads: 1. Seemingly irremovable; 2, operable, but irremovable and yet curable; 3, operable, but irremovable and incurable; and, 4, inoperable, irremovable, and incurable.

Seemingly Irremovable.

A case may seem hopeless because, for various reasons, the cancer is apparently irremovable. The case may be inoperable, yet the cancer per se may be perfectly amenable to operation. How is this so?

(1) On account of the patient's condition in other respects than as regards the cancer. If the contraindicative condition is temporary, as in the case of concurrent acute conditions, measures should be instituted for its remedy. A case which is seemingly inoperable and irremovable may be rendered both operable and removable by proper care of the patient.

If the general condition of the patient, from whatever cause, is such as to render precarious the

Fig. 2. Epithelionia and lupus crythematosus,

administration of a general anæsthetic and the subjection of the patient to the shock of a major operation, and when local anæsthesia is impossible or inadvisable, time must be given to the general up

building of strength and bodily resistance. It is necessary in such cases, of course, to exercise judgment in the matter of how long operative procedure may be delayed for this purpose without jeopard-

Fig. 3 .- Epithelioma and lupus vulgaris.

izing the patient's life by allowing the malignant process to continue too long without surgical intervention. Herein many surgeons are remiss. The cancer obscures, in their eyes, all other conditions, and a case which is easily amenable to operative procedure after due attention to other conditions, is labeled "incurable," "inoperable," or "irremovable," and the patient consigned to the outer darkness which envelops every incurable case, whether of cancer or any other disease. On the other hand, the patient may be subjected to the risk of operative procedure before due attention is given to concurrent conditions, life being thus unnecessarily endangered.

This leads me to emphasize the fact that there is no such field in surgery as that of the so called "cancer specialist." There must be a wise balancing of diagnosis before a prognosis can be justly given, and the surgeon who operates upon a patient with cancer must be able to diagnosticate and cope with any condition in the whole range of general medicine and general surgery. He must be conversant with the essential features of dermatology, of pathology, of internal medicine, of gynæcology, and so on up and down the line. It would be folly to treat the case of lupus merely as such, when superimposed upon this is an actively growing epithelioma; contrariwise, it would not be fair to remove the tongue for carcinoma superimposed upon syphilis, without recognizing and treating the latter condition. And in like manner it would be absurd for the "cancer surgeon" to perform a laparotomy for uterine cancer and not be able to recognize and give proper attention to gallstones should they be present. .. The following cases illustrate these points:

CASE IV.—Epithelioma and lupus erythematosus. Mrs. P., Italian, aged sixty, referred to my service at the New York Skin and Cancer Hospital by Dr. L. Duncan Bulkley, November 5, 1907. Patient had had ten attacks of erysipelas, the last two years previously. Following the first attack lupus erythematosus appeared on the cheeks, temporal region, forehead, nose, and ears. Five years ago she began to receive treatment for this condition. x ray and ointments

being employed, with some improvement. Three months before admission she noticed a small crust in the temporal region. From this the condition, as shown in Figs. 1 and 2, developed. On November 9, 1907, the growth was removed, and the wound skin grafted. The natient is well to-day.

region. From this the condition, as snown in Figs. 1 and 2, developed. On November 9, 1907, the growth was removed, and the wound skin grafted. The patient is well to-day. Pathological Report.—Dr. H. H. Janeway, assistant pathologist to the New York Skin and Cancer Hospital, reported the growth to be epithelioma spinocellulare.

CASE V.—Epithelioma and lupus vulgaris. Miss M. M. M. and of the seven Thic cases we want for averianting.

CASE V.—Epithelioma and lupus vulgaris. Miss M. M., aged fifty-seven. This case was sent for examination through the courtesy of Dr. George H. Fox, under whose care she had been from time to time. Tuberculosis of the cervical glands appeared at the age of two years; the glands were excised, and the resulting sinus never healed. At the age of fifteen lupus vulgaris developed at this site, extending all over the face and neck of the same side. In December, 1906, epithelioma appeared over the site of one of the curetted lupus nodules. This was treated with x ray for a number of months without benefit. When seen by me it was too late for surgical interference, the condition being as shown in Figs. 3 and 4. The patient recently died from hæmorrhage.

CASE 'VI.—Cancer of the breast and uterine fibroids. Mrs. A: F., aged forty-eight, private patient, referred to me for operation for cancer of the uterus. Right breast had been amputated four months previously by another surgeon. Shortly after recovery from this operation the patient had one or two uterine hæmorrhages, and for the first time the physician made a vaginal examination. He found a large tumor in the uterus and pronounced it a case of advanced cancer. He expressed to the husband his doubt as to the possibility of anything being done, but advised trying. I saw the patient in consultation and made a thorough examination. The uterus was retroverted, there was some fungous endometritis, and a fibroid the size of a large orange was found in the fundus. In the right side, where the drainage had been inserted at the time of the breast amputation, were a few small nodules, extending into the axilla. In the left breast was an actively growing malignant tumor, with lower axillary glands enlarged. The patient was sent away for a few days' rest in the country, and upon her return we removed the left breast, clearing the axilla, and curetted the uterus. Her condition has been much improved since the operation. A few nodules have appeared in the skin over the sternum, carcinoma en currosse, which seem to be diminishing under treatment with x ray.

Pathological Report.—Dr. Janeway reported upon the tumor from the left breast as follows: "Carcinoma of the duct carcinoma type. The tumor is very rich in cells and is very malignant. The piece of fatty tissue removed from

Fig. 4 .- Epithe'ioma and lupus vulgaris.

beneath the clavicle is involved, i. e., cutaneous carcinoma." The scrapings from the uterus showed simple endometritis. CASE VII.—Ovarian cyst; ovarian cancer; chronic appendicitis; gallstones. Mrs. J. L., private patient, aged forty-six years. Admitted to the New York Skin and Cancer Hospital, April 29, 1907, for operation for removal

of an ovarian cyst of the proportions shown in Fig. 5. She had complained of headache, pain in the back, a dragging sensation on walking or standing, enlargement of the abdomen, and occasional vomiting.

Operation April 30, 1907. Through a median incision a

Fig. 5. Ovarian cyst with caremonia of other ovary and gallstones.

globular fluctuating cyst was found to spring from the right ovary. A canula was introduced and sufficient fluid withdrawn from the cyst to allow of its removal through a moderate sized wound. The broad ligament was then clamped off and the cyst, with right ovary and tube, severed and removed. The cyst weighed twenty-six and one half pounds. The left ovary contained small cysts, and was the seat of a tumor the size of a hickory nut, which suggested-beginning carcinoma. The left ovary was excised, and the tube left. The appendix, which was bound down by adhesions, was removed. The gallbladder was found much distended and containing gallstones. The gallbladder was found much distended and containing gallstones. The gallbladder was stitched into a vertical cholecystostomy wound just below the edge of the ninth costal cartilage. Two days later it was opened and fifty gallstones removed. drainage was allowed.

Pathological Report.-Dr. Martha Wollstein pronounced

Pathological Report.—Dr. Martha Wollstein pronounced the tumor of the left ovary to be carcinoma.

Case VIII.—Gumma of tongue. J. T., male, aged thirtyone, admitted to the New York Skin and Cancer Hospital, June 19, 1907. Negative luctic history given. Nine months before admission patient naticed a small "sore" at base of tongue, near the centre of the dorsum. During my absence from town the diagnosis of cancer of the tongue was made by six different doctors. When I returned the patient was on the table, ready to be anæsthetized for operation for removal of the tongue. I made an examination and found the condition shown in Fig. 6. A deep ulceration, about one inch wide, extended backward from the posterior two thirds of the dorsum of the tongue to the epiglottis. The edges were irregular and elevated, and the floor uneven and coated. The edges were soft and friable, and from this portion sections were removed for microscopical study. Cervical and supraclavicular glands were enlarged. I re-fused to operate, and immediately placed the patient upon antisyphilitic medication, with the result that the ulceration completely disappeared. The correctness of my diagnosis was further shown by the pathological reports from Dr. Martha Wollstein, of the Rockefeller Institute, and Dr. H. H. Janeway, assistant pathologist to the New York

Skin and Cancer Hospital, both of whom rendered negative reports so far as cancer was concerned, each suggesting quiescent tuberculosis or syphilis as the probable condition. No tubercle bacilli were found; Spirochætæ pallidæ not stained for

I need not dwell upon the horrible mistake that would have been made had the diagnosis of cancer been accepted and the patient's tongue extirpated, as would have been necessary with a cancer of such proportions and duration.

(2) Concurrent complications in the neighborhood of the cancer may lead to the diagnosis of irremovable malignancy. There may be tissues in the neighborhood which are involved in inflammatory reaction, neighboring glands may be the seat of pus collections, and various other complications may for the time obscure the prognosis in the minds of those not skilled in such matters. Even the expert should be on guard against error. Under such circumstances both the complication and the cancer itself are sometimes neglected because of the seeming hopelessness of the condition. Many times the cancer may be complicated by septicæmia or sapræmia, and it may be this condition more than the cancer which for the time overwhelms the patient. The following case illustrates this point.

CASE IX.-Epithelioma of foot; femoral abscess. Mrs. A. D., aged fifty-four, admitted to the New York Skin and Cancer Hospital March 23, 1908. Three months previous to admission she first noticed a small growth on the dorsal surface of the left foot, just in front of the external malleolus. This grew to about the size of a walnut. On the same side the glands in the inguinal and femoral regions recently became enlarged, an acute infection along the line of the cancer invasion resulting in a large fluctuating mass in the left groin, with the systemic symptoms of sepsis.

The physician in charge diagnosticated the entire condition as one of rapidly disseminating cancer. On admission the distinctive diagnosis was made of cancer of the foot, with slight metastasis in the groin, and with large abscess in the femoral region. The abscess was opened, and as soon as the pus was evacuated the patient made a rapid con-

I to, 6.- Syphilis diagnosticated as cancer

valescence from the acute symptoms, marked relief being secured. Since that time the cancer of the foot had been removed and the glands in the groin extirpated. The patient still had some cancer, but she was able to leave the hospital in very much better condition.

Pathological report showed the tumor on the foot to be

epithelioma and the glands to be carcinomatous, but the condition from which the patient suffered most was the sepsis.

(3) Cases are sometimes consigned to the inoperable and hopeless class because of the risk to the

Fig. 7.—Carcinoma.

patient from operative procedure seems too great to be incurred because of the extensive involvement, as well as on account of the patient's lowered vitality. The risk is undoubtedly too great in many cases, but fortunately in many others it is not. Unfortunately, however, in many of the latter instances patients are given up to die who, by timely intervention, might be literally snatched from the grave, to live years thereafter, absolutely free from the disease.

To this latter class belongs a patient who had an extensive carcinoma of the tongue and neck, whose case has been previously reported. The patient has been presented at each of the annual clinics and upon other occasions, for several reasons: First, because, so far as I am aware, he represents a case of the most extensive surgery of the mouth and neck on record; second, because of the persistent reports that the patient has succumbed to the inevitable; and, third, because it has been charged that, "after all, it was not a case of cancer, or the patient would not be alive."

CASE X.—There was in this case extensive involvement of the tongue, floor of the mouth, and glands of the neck, and when first seen the patient was in no condition to undergo as extensive an operation as eradication of the disease entailed. For the time being he certainly was inoperable and the cancer irremovable. By a few days of rectal feeding, improving the condition of the mouth, flushing out the kidneys and toning up the whole system, the margin of danger was lessened, and while the risk was very great, the patient determined to take the chance.

The submaxillary and sublingual glands on each side were removed, the salivary ducts were extirpated clear into the mouth, and many cancerous glands from the tonsils to the dome of the pleura on one side and to the division of the carotid artery, on the other, were dissected out. Two weeks later the entire tongue, floor of the mouth, and most of the soft palate were completely excised. Both lingual arteries were tied, and all lymphatic and connective tissue in juxtaposition to the disease removed.

This was done in March, 1904, and the patient is perfectly well and strong to-day, with no sign whatsoever of

a recurrence of the disease. He was present at the clinic and spoke in the hearing of all.

The published pathological reports of undoubted cancer, given by two independent pathologists of distinction, refute the statement above referred to that the disease was not malignant.

Operable but Irremovable, yet Curable.

The word curable as applied to cancer is, as one may readily appreciate, a relative term. Strictly speaking, we do not cure the cancer-we remove it; and in the vast majority of cases, when it is impossible to remove the cancer, it is impossible to effect a cure of the patient. This is in line with the statement previously made that to-day surgical procedure is the only dependable means of eradication of malignancy. Then, too, there are those who hold that it is impossible to fix a time limit upon recurrence, and who deny that if the disease does not return in three or five, or any number of years, the case may be pronounced cured. On the other hand, statistics amply justify the so called three year limit. However this may be, we know that in a very limited number of cases cancer disappears of itself, with no further manifestations of the disease. This is common in mouse cancer, thirty per cent. of those which have been recorded being said to heal spontaneously. In man it would be more than foolish to fold our hands and wait patiently for an epithelioma or a sarcoma to disappear spontaneously because so called cancer in mice is said to do so in such a large proportion of cases. We must remember that it is a serious question whether cancer in the mouse is at all analogous to cancer in man, and we do know that spontaneous cure in the human subject is extremely rare.

In still another limited number of cases of advanced cancer which is operable, but in which it is impossible to remove the entire growth, by removing as much as possible and instituting other measures, Nature seems to be able to cope with the malignant process and to reduce it to such a state of subjugation that it disappears or remains so completely

Fig. 8.-Carcinoma.

quiescent that the patient lives a number of years, and is to all intents and purposes cured. Dawbarn, in his book on the Starvation Treatment of Certain Malignant Growths. relates such cases. In one of these, the first in whom he operated by this method,

American Medicine, March 25, 1905, and Atlanta Journal Record of Medicine, June, 1905.

and the first reported in his book, the operation was performed on June 1, 1895, and on going to press, March, 1903, eight years later, the patient was perfectly well. In this case a round celled sarcoma involved the nasopharynx, filling both nares, rendering deglutition and respiration difficult, and interfering It caused severe headache and with articulation. dizziness, and bled profusely upon the slightest touch. The patient had been treated, previously to consulting Dr. Dawbarn, with injections of the mixed toxines of Bacillus prodigiosus and Streptococcus erysipelatosus, with no good effect upon the tumor. Another surgeon, whose name Dr. Dawbarn withholds from publication, declined any intervention whatever, pronouncing the case hopeless. With the idea of giving temporary relief to the dyspnæa and dysphagia, Dr. Dawbarn tied off the right external carotid artery at its origin in the hope of shrinking and starving, for a little time, the growth. Subsequently the more radical operation of complete excision, from end to end, of the left external carotid artery was performed, its eight branches successively being tied and divided between two ligatures. This was the first time the operation was ever performed, and the results in this and many other cases are certainly monuments to radicalism in cancer surgery.

Dr. Dawbarn's method was later modified by Dr. Wveth, who introduced the idea of injecting boiling water or some plastic substance, such as paraffin, into the terminal branches of the external carotid. I have employed this procedure in a number of cases with satisfactory results.

It is sometimes possible, also, by other measures to effect a cure where the growth is removable only in part. The following case illustrates this:

CASE XI.—Melanotic sarcoma. G. W. C., aged forty-four, admitted to a private hospital in this city in December, 1902. For a number of years a mole, about the size of a French pea, slightly pigmented, had been present on the posterior surface of the left wrist. One year before admission this was irritated and infected, following which an abscess formed in the axilla. The mole was incised and the axillary abscess opened. The wound in the wrist healed but a discharging sing remained in the axilla. healed, but a discharging sinus remained in the axilla. At the time of admission there was an indurated mass the size of a hen's egg in the axilla, and a great deal of inflammatory tissue in its neighborhood. The patient was poorly nourished and anaemic. All inflammatory tissue, with the involved lymphatic nodes, and the walls of the sinus, were removed en masse. The disease was found to extend well up to the clavicle, occupying Mornheim's space above and completely surrounding the subclavian vein to its entrance into the chest. The axilla was thoroughly cleared, but it was impossible to remove all the disease. The outer surfaces of the ribs were scraped, and the external intercostals, which were evidently diseased, were curetted for some distance. The wound was closed except for a drain at its most dependent portion. The ulcerating, indurated mass on the wrist was excised, with a margin of healthy tissue. The patient was discharged in two weeks, and has re-

mained well ever since, with perfect use of his arm.
Pathological Report.—Dr. Martha Wollstein reported "melanosarcoma of an axillary lymph node."

Between the second and third classes, namely, the operable and irremovable, yet curable, and the operable, irremovable, and incurable, may be placed the

following case:

CASE XII.—Malignant papillomata. R. V., aged twenty-nine, married, housewife. Patient had had an exploratory laparotomy performed previous to consulting me,

he Dissbarn inform me that when last heard from, in 1907, the patient was still perfectly well.

the clinical diagnosis of round celled sarcoma being made at the time. She first consulted me May 18, 1907. Clinical evidence did not, in my opinion, justify the diagnosis given, and an exploratory laparotomy for diagnostic purposes was performed June 12, 1907, in the New York Skin and Cancer Hospital. Papillomatous degeneration of the uterus, tubes, and ovaries was found, extending to the intestines and well up toward the liver. A detached portion was removed for microscopical examination, the report being "malignant papilloma." Ten days later panhysterectomy was performed, and a large amount of fluid evacuated. A large papillomatous mass in the pelvis was also removed.
On November 12, 1907, I performed a third laparotomy for the purpose of removing fluid and more papillomatous masses. On January 11, 1908, a similar operation was performed. At this time there was less fluid and a distinct decrease in the number of papillomatous nodules. On March 6, 1908, the patient returned to the Skin and Cancer Hospital, when paracentesis abdominalis, under local cocaine anæsthesia, was made, and eleven pints of serosanguinous fluid evacuated. On April 14, 1908, the last operation was performed, when fluid was evacuated and more of the papillomatous masses removed. No abdominal adhesions were found upon this occasion.

At each successive operation the papillomatous degeneration was found to be less extensive, and the ultimate out-come of the case will be watched with interest and the case reported more in detail later. At each of the last four operations oxygen gas was introduced into the abdominal cavity, this feature of the case being reported in the New York State Journal of Medicine, June, 1908.

Operable but Irremovable, and Incurable.

The cases which come under this head may be inoperable so far as complete removal of the diseased tissue is concerned, and yet much may still be accomplished by surgical and other means to relieve suffering, lessen fœtor, and prolong life.

The management of these cases may be considered

under the following heads:

(I) Treatment of the patient, as we have before suggested. In many instances the patient is cachectic more from the locking up of the secretions by physical inactivity, by insufficient or improper food, and by morphine than by the disease itself. A well person, given equal amounts of morphine and having the bowels and all the secretions locked upthereby, might have an almost cancerlike cachexia. All this should be attended to, and the emunctory organs made to functionate as well as is possible under the circumstances. Tonics, digestives, good food, plenty of air and sunshine, will do much toward helping the patient to fight the battle to the

(2) Treatment of the indirect conditions caused by cancer. A malignant tumor may cause obstruction of the nose, for example, of the œsophagus, of the stomach, etc., and to relieve this obstruction it may be necessary to resort to tracheotomy, esophagostomy, gastrostomy, enteroenterostomy, etc., as the case may be. In case of obstruction of the bladder suprapublic cystostomy or perineal drainage may be necessary. The following is a case in point:

CASE XIII.—W. A. R., male, aged thirty-four, admitted to the New York Skin and Cancer Hospital January 15, 1908. A mass was found in the right side of the neck the size of an orange, and in the left the size of an egg, each of about two years' duration (Figs. 7 and 8). These masses were so located and of such size as to prevent the patient from opening his mouth freely, and to cause marked dysphagia and cyanosis. It was impossible to remove all the diseased tissue, but two operations were performed and enough obstruction relieved to give the patient much greater comfort. In fact, his condition was so much improved that he was confident of ultimate recovery. On April 18, 1908, his breathing became very bad and it was necessary to resort to rectal feeding. I assured him that it would be necessary to insert a trachectomy tube in order to prolong his life, but so sure was he that he would recover, and with the belief that the trachectomy would interfere with his profession of playing a wind instrument, that he refused his only chance of life, and died two days later. Had he consented to the trachectomy operation his life might have been prolonged for many months.

An irremovable tumor in the axilla, either a primary growth, or, more frequently, a recurrence following mammary cancer, may, by pressure upon the lymph vessels, cause marked and painful swelling of the arm, the condition being sometimes known as "big arm." Mr. Handley, of Middlesex Hospital, London, has recently devised a simple operation for the relief of this condition. The swollen arm is drained by a number of buried silk threads, which, by capillary attraction, carry away the excess of fluid.

When the growth presses upon nerves, causing the most excruciating pain, this may be relieved by cutting the nerves pressed upon. In a number of instances of cancer of the floor of the mouth I have cut the branches of the inframaxillary division of the fifth nerve, giving great relief.

Case XIV.—An instance of this is the case of a man, thirty-five years of age, who consulted me in December, 1907, with irremovable cancer of the floor of the mouth and back of the throat. The pain was intense, and by cutting the nerves on both sides the patient was greatly relieved.

(3) Tying off blood vessels in the carotid region. Dawbarn's method, already mentioned, aims at checking the malignant process by cutting off its blood supply; this is also applicable in the carotid region for the control of hæmorrhage, and the furtherance, thereby, of whatever other methods of treatment may be applicable in the individual case. The growth may so erode vessels that the slightest manipulation is liable to cause a rupture of the wall of the vessel and consequent hæmorrhage. A case in point is the following:

Case XV.—M. W., male, aged forty-eight, admitted to the New York Skin and Cancer Hospital April 1, 1908. Examination revealed a cyst the size of a hen's egg, with a mass of induration underneath it seemingly fixed, in the submaxillary region on the left side. Inside the mouth was a fungoid mass attached to the inferior maxillary bone and the left inner side of the cheek. This bled readily, and caused an excessive flow of saliva. For a year and a half his jaws had been very stiff, and when examined he could open his mouth only half an inch. He suffered severe pain, especially at night. Examination under an anæsthetic showed the entire left inferior maxillary bone, mucous membrane of the left cheek, and submaxillary glands to be involved, and the floor of the mouth was filled with cancerous material.

On April 11, 1908, the submental, submaxillary, and superior carotid triangles were explored. In the submental region a tumor mass the size of a hen's egg, which was closely adherent to bone and fascia, was excised. The submaxillary lymph glands were involved and were removed. On account of the extent of the disease an incision was made down close to the external carotid artery before the mouth was opened at all. When the mouth was opened rupture of one of the ulcerated vessels occurred, and immediately there was a terrific arterial hæmorrhage, which undoubtedly would have proved fatal in a few minutes but for the timely tying off of the external carotid. The hæmorrhage was controlled by this means and the operation was continued. In addition to the external carotid the sublingual, superior thyreoid, ascending pharyngeal, facial, and posterior occipital were tied off separately. The patient's condition was so poor and the vessels so ulcerated that I thought it wise not to inject paraffin at this time. Subsequently the external carotid of the opposite side was in-

jected with paraffin and all the branches, with the exception of the two terminals, tied off.

(4) Tying off vessels in the pelvis, in inoperable uterine and other pelvic cancer, lessens the danger of hæmorrhage, decreases fætor, and renders it possible to proceed with the necessary surgical intervention, such as curetting, cauterizing, etc. It also diminishes the rapidity of growth in some instances, lessens pain, and frequently prolongs life. The ovarian and uterine arteries, or, if the uterine cannot be reached, its nearest branches, may be tied off; or the anterior division of the internal iliac may be ligated on the side of the most extensive disease, the uterine and ovarian of the opposite side being ligated at the same time. The ovaries are removed in each case.

This procedure has been successfully applied in the following cases, among many others:

CASE XVI.—Mrs. F. W., aged thirty-nine, admitted to the New York Skin and Cancer Hospital, June 22, 1907, with advanced cancer of the rectum and vagina. The anterior rectal wall and the diseased portion of the vagina were exsected. Patient made an uneventful recovery, and remained in fair condition until February, 1908, when she returned to the hospital, complaining of great weakness, insomnia, pelvic pains, and frequent micturition. Operation February 7, 1908. Uterus, both ovaries and tubes, adjacent portions of broad ligaments, and bladder were found to be the seat of extensive cancerous disease. The uterus was so involved that operative procedure upon this organ was impossible. The uterine arteries could not be reached, but both ovarians were ligated, and both broad ligaments near the wall of the pelvis were also constricted by ligature, with the hope of shutting off the blood supply to the uterus. Both ovaries and tubes were removed. Patient's condition at the present time very much improved. She is able to be up and about, and is comparatively comfortable

be up and about, and is comparatively comfortable.

CASE XVII.—Mrs. M. D., aged fifty, admitted to the New York Skin and Cancer Hospital November 29, 1907. Irremovable carcinoma of cervix, with secondary involvement of the body of the uterus and the broad ligaments; extensive adhesions. Operation December 5, 1907. Profuse hæmorrhage resulted from attempts to isolate tubes and ovaries. In order to control this the ovarian arteries and the upper branch of the uterine artery were ligated. It was impossible to reach the uterine artery itself on account of adhesions. Both tubes and ovaries were removed. Further operative measures were impossible on account of extensive involvement of the body of the uterus, broad ligaments, rectum, and pelvic fascia. Patient was discharged December 30, 1907, in fair condition. At the time of the clinic she was able to be about, and though going down hill, she was certainly better than she would have been without operation.

(5) Other methods than surgery may be employed in this class of cases with appreciable benefit in some instances and with some of the measures usually adopted. The name is almost legion of agents which have from time to time been exploited for the cure, first, and then for the amelioration of cancer. With our position perfectly clear, namely, that, barring a few superficial growths of small size, the only means of cure is found in surgical procedure, we may safely consider some of the measures which offer possibilities for amelioration.

A.—X ray undoubtedly occupies a limited field of usefulness in irremovable cancer, as an adjuvant to other measures. It may lessen pain and foetor, check the ravages of the disease to a certain extent, and help, by its psychic effect and otherwise, to make the patient more comfortable. It is at times useful in the treatment of secondary superficial skin involvement, causing the absorption of nodules of metastasis.

I cannot refrain, however, in this connection, from sounding a protest against the indiscriminate use of x ray, alone or with various other measures, when more effective methods may be employed. There is never, from the incipiency of the malignant process, any time to lose with doubtful agents, but there comes a time when such delay is deplorable in the extreme, and even fatal to life. In this institution we see the end results of such methods, and it is borne in upon us more and more that they should, with the exceptions above noted, be confined strictly to purposes of amelioration in cases not amenable to surgery.

B.—High frequency current, by its effect upon the general system, has some beneficial influence upon the patient rather than upon the cancer, and when practicable it may be well enough to add this

to the adjuvant treatment.

C.—Fulguration, the application of high potential, high frequency electricity, has attracted more or less attention recently, particularly in France, through the work of de Keating-Hart, who first suggested it. The patient is profoundly anæsthetized and a sharp point discharge sent into the cancer. It is supposed to act as a powerful cauterant, burning away the sloughing and broken down tissue. It is not intended to take the place of any curative agent, though it has, like other palliative measures, been employed in cases which were amenable to surgical treatment. Its use is also limited to external cancer. Czerny and others who have employed this method report favorably upon its effects in the class of cases mentioned, holding that it is more effective than radium or x ray.

D.—Leucodescent light has proved of some benefit in the amelioration of pain in cases of the class

under discussion.

E.—Radium is still employed by a few persistent advocates who allege to have wonderful results from its use. It has been faithfully tried in this hospital, and cast aside as accomplishing nothing that cannot be more satisfactorily effected by other methods. For the removal of small, superficial growths it is sometimes effectual, leaving a very good scar, but in cancer it has done far more harm

than good.

F.—Mixed toxines of Bacillus prodigiosus and Streptococcus erysipelatosus (Coley's fluid) is another agent which has clamored vociferously for attention and approval since 1891, when Coley published his original observations. It is now limited to the treatment of certain types of sarcomata, and should be confined to the treatment of inoperable cases, but, like x ray, radium, and the rest, it has been used in many cases which should have been subjected to surgical intervention. Even in inoperable cases, however, its value seems to be far from established.

G.—Streptococcus pyogenes (Wyeth). Dr. Wyeth has for a number of years employed the toxines of the Streptococcus pyogenes in inoperable cases of sarcoma, reporting a number of favorable results. We are using this method in two cases of my service at the New York Polyclinic Medical School and Hospital at the present time. The first patient is a child two years of age, with osteosarcoma of the radius. The condition is perfectly amenable to surgical treatment, but because of the

refusal of the mother to consent to the necessary operation, amputation of the arm, the child is placed in the inoperable, irremovable, and, if this treatment is ineffectual, in the incurable category. The other case is a woman, thirty-five years of age, with a sarcoma the size of her head, in the neck.

H.—Oophorectomy (Beatson), for inoperable cancer of the breast, has been advocated, either with or without the administration of the extract of thyreoid gland, the object being to facilitate the fatty degeneration of the cancer elements. In some of the cases reported by Beatson and others results have been favorable, the disease completely disappearing. In others recrudescence has followed the disappearance, and in still others the method has met with no success whatever. Inasmuch as it is a serious matter to subject a patient with inoperable cancer of the breast to such an operation, the method has not met with extensive approval.

I.—Pancreatic enzymes. In our efforts to find something which will lead to the dawn of a better day for the cancer sufferer, when something will appear which will relieve us of this terrible scourge and eliminate the disease without the necessity of recourse to surgery, we are constantly reaching out for the newer methods which give us any reasonable hope of fulfilling the promises made for them. New candidates for favor are constantly presenting themselves, and one by one they reach their rightful place of complete elimination, or are confined to the palliative treatment of incurable cases. Of these the pancreatic enzymes, trypsin and amylopsin, with the adjuvant treatment, are conspicuous examples. For many months past we have been trying this method in this institution and in private practice, giving it a fair and accurate test. In the autumn a full report of two years' experience with the treatment will be published, but at present the question is sub judice.

In addition to the methods I have mentioned several other agencies are at present receiving more or less attention, among which may be mentioned inoculation with the various other gland products, the thyreoid, thymus, liver, etc.

Inoperable, Irremovable, Incurable.

We come now to the last division of our classification, the cases in which everything that is possible has been done by surgical means, in which all hope of cure is gone, and in which our sole aim is to alleviate the suffering of the patient and the discomfort of those about the patient, by lessening the feetor and discharge. It is well known that some of these individuals live a number of years with what the laity call an "eating cancer," and those years, or whatever the length of remaining life, should be made as comfortable as possible. What I have said about treating the patient applies even more to this class than to the others. Every care and attention should be given to such patients to help them bridge over the remaining span of life. So far as cancer itself is concerned, attention is chiefly directed to lessening pain, fector, and discharge.

Pain may, to a certain extent, be controlled by morphine, always to be counterbalanced by something to offset its bad effects. If there is sweating, atropine may be given with it, or if it is to be given over long periods of time it may be admin-

istered in the form of the U. S. solution with clivir of lactopeptin. Acetphenetidin, 10 to 15 grains twice daily, will sometimes be sufficient to control even severe pain and to make the patient fairly comfortable. Antipyrine and acetanalide may also be used. The depressing effects of the coal tar products should be modified by stimulants.

Alcohol, in moderation, taken with food, may be useful. The diet should be wholesome and varied. There is almost invariably a tendency to hyperacidity in these cases, hence alkaline waters should be given. Intestinal antiseptics and antacids are help-

ful.

The fungating masses should be kept clean by frequent dressing. The galvanocautery, zinc chloride paste, and lotio pancreatis applied locally will help to keep the surfaces clean and to lessen fœtor. It must not be forgotten, however, that while pastes and even lotio pancreatis may smooth off the surfaces, they may at the same time erode blood vessels and thus give rise to severe and perhaps fatal hæmorrhage. Where the cancer has eaten its way through, leaving openings, as in the pharynx or base of the mouth, the compound tincture of benzoin with nosophen or arystol (Bainbridge's modification of Whitehead's shellac) can be used to plug the openings. Adrenalin chloride is also useful. Terchloride of antimony will help to check hæmorrhage and lessen fœtor in advanced uterine cancer after the vessels have been tied off and as much of the disease removed as possible.

It should be borne in mind that the discharges are often offensive far more from the action of putrefaction or pyogenic organisms than from the cancer itself, and attention should be directed to keeping the surfaces clean by the use of various antiseptic ointments and washes. Deodorizers, incense, etc., may be used in the room to make the atmosphere less

disagreeable.

Irremovable cancer is a difficult and many times discouraging condition with which to deal, and the surgeon who is trying to keep down his mortality records and to swell the list of brilliant surgical feats, is not apt to consume his valuable time with incurable cancer; yet the physician or surgeon who fails to do the very utmost for such patients who may confide themselves to his care, or to refer them to those who will give them the proper attention, is false to his Hippocratic oath as well as to his duty to his fellow man.

34 GRAMERCY PARK.

THE INTERNATIONAL CLASSIFICATION—ITS ADVANTAGES, DEFECTS, AND

DEFICIENCIES.*

By Cressy L. Wilbur, M. D., Washington, D. C., Chref Statistenan, Bureau of the Census

I have been asked to prepare a paper for the section under the above title by the chairman of the Committee on Programme, and gladly embrace the opportunity because the question of revision is now upon us, and a year earlier than we anticipated a short time ago.

It is not necessary to say that I refer to the International Classification of Causes of Death—and Sickness.' One of the brightest pages in the long and honorable history of the American Public Health Association is its early indorsement of the International Classification, at a time when the movement was weak, and without which the general extension of this system, which appears to be the only hope of securing uniform and thoroughly comparable statistics of causes of death and illness throughout the world, might have perished. Or, rather, might have been postponed for many years, for it must inevitably come.

At the meeting of the American Public Health Association at Ottawa in 1898 the following resolution was adopted, after a year's consideration:

Resolved. That the American Public Health Association recommends that the Bertillon classification of causes of death be adopted by all of the registrars of vital statistics in the United States, Canada, and Mexico, as soon as the changes from the systems now in use can be conveniently made.

At the recent meeting of the American Medical Association at Chicago, June, 1908, the House of

Delegates unanimously voted as follows:

Resolved, By the American Medical Association:
1. That the International Classification of Diseases and Causes of Death be recommended for all official mortality and morbidity statistical reports.

2. That the Committee on Nomenclature and Classification of Diseases present a report on the Nomenclature of Diseases of the Royal College of Physicians of London to the Association at its meeting in 1909, with such recommendations as may seem advisable for American usage, and with the assignment of each term indicated according to the International Classification.

3. That a tentative reconstruction of the International Classification be framed on the basis of the foregoing report, and recommendations be drafted for submission to the International Commission of

Revision.

4. That inquiry be made as to the possibility of holding the next Decennial Revision of the International Classification at Washington in 1910 in connection with the International Congress of Hygiene

and Demography.

5. That after the revision of the International Classification in 1910 the nomenclature of diseases be recast in corresponding form, so that there will be available under a uniform arrangement and with precise agreement in the meaning of terms: (1) International classification of causes of death; (2) international classification of sickness and disability: (3) international nomenclature of diseases and injuries.

At the time of the adoption of these resolutions it was supposed that the date of the second decenial revision would be 1910. You may recall, however, that in my paper presented to the American Public Health Association two years ago, some reasons were given why it was desirable that the revision should be conducted in the years 1909, 1919, etc., rather than in the years 1910, 1920, etc., and

^{*}Read before the Section in Vital Statistics of the American Pullic Health Association at the thirty-sixth annual meeting, held in Wimiting, Catasha, on American 12, 1, 18, 1808

^{&#}x27;I have not referred to the application of the International Classification to morbidity and hospital statistics because this subject comes in the special province of Major Mason, representing the medical describes to the United States army, which has employed and the control of the United States army, which has employed and the control of the United States army, which has employed and the control of the United States army, which has employed and the Control of the United States army, which has employed and the Control of the United States are control of

very shortly after the date of the Chicago meeting of the American Medical Association an announcement was received from Doctor Bertillon of which the following is a translation:

Direction des affaires municipales, Statistique municipale, 1, Avenue Victoria, Parts, June 1, 1998

Sir and Honored Confrère:

I have the honor of forwarding to you a copy of the International Classification² of Causes of Death, in use in a large number of countries. I shall be grateful if you will make a careful examination of it and transmit to me the critical observations that may suggest themselves to you. These remarks will be studied, classified and collated in order that they may be submitted for examination by the International Commission charged with revising the classification.

This Commission will hold its second session in the

course of the following year.

The following is a brief outline of the history of the

At the instigation of several scientific societies, notably the American Public Health Association, the International Statistical Institute, etc., the minister of foreign affairs of France invited the different powers to send representatives to a commission charged with drawing up an international classification of causes of death, with the purpose of rendering nosological statistics comparable among the different countries. The classification adopted by the International Statistical Institute was previously submitted to the examination of a large number of statistical authorities. Their observations were classified and printed in the form of a brochure in order to serve as a basis for the final examination of the commission. Twenty-six countries accepted the invitation of the minister of foreign affairs; the commission, composed enminister of foreign analys, the commission, composed circly of official delegates, was in session during the 18th, 19th, 20th, and 21st of August, 1900, and after a thorough examination adopted the classification a copy of which I am forwarding to you. It declared that it was desirable that its work should be revised every ten years, in the absence of the course of the appropriate and it requested that sence of any other arrangement, and it requested the French government to see to convening the commission. I have been especially empowered to take the necessary measures.

Quite recently the officials of the Census of the United States expressed the desire to have this date advanced by one year, on account of the census, which is to take place in the United States and in a great many other

countries, in 1910.

As a great many other countries considered the mat-ter in this light, and as no country has opposed the plan, the minister of foreign affairs of France has informed

plan, the minister of foreign affairs of France has informed me that his department makes no objection to the choice of the year 1909 for assembling the commission.

The International Classification has been adopted by all of the countries of North America, by nearly all those of South America, by all the countries of Australasia, by Japan, by the countries of Western Europe (Spain, France, Delaying Lighted the Countries of Mestern Europe (Spain, France, Countries) Belgium, Holland, etc.), by some others (Bulgaria, etc.), and by several cities of Austria and Russia.

I shall be glad to receive your observations and criticisms before the first of November following.

Very respectfully yours,

DR. JACQUES BERTILLON, Chief of Statistics,

Secretary General of the First Session of the International

Immediate action is therefore necessary, instead of the more leisurely procedure that would have been possible if the year had remained 1910, and we are very fortunate that there is now a thoroughly organized General Committee on Nomenclature and Classification of Diseases and Causes of Death constituted by the American Medical Association in 1907 and continued in 1908, which is actively cooperating with the committees of other national organizations in the United States, with the Committee on Causes of Death and Revision of the International Classification of this section of the American Public Health Association, with the government medical services (Army, Navy, and Public Health and Marine Hospital Service), and with the Bureau of the Census.

The exact plan of organization of the International Commission of Revision, which will meet at Paris next year, cannot yet be stated, except that. as in the session of 1900, each country will be repre-

sented by official delegates.

With this preliminary statement, I shall now proceed with the special subject of the paper. Any suggestions made should be considered as entirely informal, although they will be submitted for the consideration of the general committee, and some of them may perhaps be regularly included in the recommendations for the revision.

Advantages of the International Classification.

The chief advantage of the International Classification is the fact that it is truly international. It is in practical use, according to Doctor Bertillon, in twenty-two different countries, and gives for them readily comparable results." The ease with which statistics of causes of death from countries using this system may be compared, and the difficulty of reducing dissimilar systems to a common denominator, may be seen in the international tables of causes of death published by the French government. No further argument is necessary under this head.

The above statement may be taken as referring to the printed tables of statistics, in which the causes of death are ranged in order after compilation. For the practical work of a registration office the question is, How are they compiled? What terms found in the returns of deaths are listed under each title? The International Classification takes us behind the scenes in this respect as no other system does, and while the results may undermine to some extent any preconceptions as to the infallibility of official statistics of causes of death, they point out the only way in which such statistics may ultimately be placed upon a thoroughly sound basis.

Lastly, for I shall not go into detailed comparisons of the titles and arrangement of the International and other classifications, we have—thanks to the original suggestion of the American Public Health Association-provision for a regular decennial revision, with the cooperation and active participation of the registration offices of the countries using the system, whereby any of the defects and deficiencies of which I shall come to speak, many of which arise from the increase of knowledge during the past ten years rather than from any fault of the commission of 1900, may be readily eliminated.

Defects and Deficiencies of the International Classification.

These terms are to some extent synonymous. The International Classification is deficient or in-

ferable trace internationals," proposity used in French is pre-ferable trace and "international clevidity, and in the course Music I not instantian Termin (analy), rather than "international gomenclature." A nomenclature of diseases is a guite different prey char of the Royal College of Physicians of London

Bulletin de l'Institut international de statistique, xvn. 4, 1907. Statistique generale de la France, 1907.

adequate in some respects, and this of course constitutes a defect. It has also certain marked defects or blemishes. I shall not attempt to maintain this distinction, but shall first consider some of the general features in which we might make some improvement, and then proceed to the consideration of desirable changes in titles and in the individual terms included under them. For this is to be constructive, not destructive, criticism; and it is desirable that every user of the statistical tables of causes of death shall at this time call attention to every feature that requires amendment so that the suggestions can be considered in the work of revision. And thereafter, for the next ten years, let us hold our peace and loyally use the revised system until the time shall again come for the regular decennial revision. It is just as important that we shall have a fixed basis of statistics between the dates of the International Revision as that we shall bring the system strictly up to the latest knowledge when that work is undertaken. If every office using the class-ification is free to make individual modifications during the interdecennial period, the statistics soon become uncertain, and we shall lose the chief advantage to be gained from international uniformity and conformity. Hence let us make the revised classification as nearly right as possible in 1909, and then leave it strictly alone until 1919.

General Criticisms and Recommendations.—The order of titles and the arrangement of titles under general classes ("classification" in the narrow sense) are matters of subordinate importance. The principal thing is to insure the definiteness of the

individual titles.

There are too many insignificant titles, indefinite in character and including only a small and negligible number of deaths. It would be desirable that the extended list of causes of death be reduced to as few as 100 separate titles, instead of 179 as at present, and that a well selected list of this length be generally used instead of the abridged list of only 35 titles. For monthly bulletins and special purposes a condensed list of 15 or 20 titles might be employed, but a reasonably detailed list should be used for all annual reports.

A list of 100 titles should suffice for all general morbidity statistics, but for hospital reports, in which the forms of statement are under control, more exact and specific information may well be given. An expanded list of 1,000 titles would probably suffice. This should be perfectly reducible to the standard list of 100 titles, and the titles of the abridged list should also exactly correspond to titles

of the standard list.

The same title should always mean the same thing and possess the same inclusion of terms wherever

A statistical classification must meet two important but conflicting purposes, namely, (I) to give information in regard to the occurrence of the most important causes of death, such as tuberculosis, pneumonia, violence, etc., and (2) to note the occurrence of rare causes of death, some of which, however, may become of occasional epidemic prevalence; among these are such diseases as plague, leprosy, yellow fever, pellagra, all of which may be endemic in certain localities.

It is desirable that the standard classification should not be cumbered with the titles of certain diseases of only rare occurrence or of small numerical importance, but at the same time the list should show with certainty whether any of these diseases did or did not occur during the period covered. In the event of their occurrence, special subsidiary tables should be given with full detail for each disease, as is done for plague, leprosy, distomiasis, etc., in the reports of Japan. A plan to meet these desiderata should be devised if possible.

In regard to the causes of major importance, such as tuberculosis, pneumonia, cancer, heart disease, nephritis, etc., a careful revision is necessary so that indefinite returns may not vitiate apparently definite statistics. If the distinction is to be maintained between lobar or croupous pneumonia and bronchopneumonia, then a return of "pneumonia" (unqualified), which might be either bronchopneumonia or lobar pneumonia, should not be included with either but should be stated separately. "Tumors" of certain organs are apparently subjected to a different principle of classification than that applied to cancers; probably all neoplasms should be brought together, and the statement of organ affected, both for cancers and other tumors, should be so made that the total for each important organ can be obtained. At present, for example, the "other diseases of stomach" (104) exclude cancer and also tumor of stomach (40), while "diseases of the bladder" (123) exclude cancer but include tumor of the bladder. So large a proportion of the deaths reported from "heart disease," "heart trouble," etc., is of doubtful value as indicating actual organic disease of the heart that a subdivision of title 79, "organic diseases of the heart," into (a) definitely stated valvular and other cardiac lesions, and (b) indefinitely reported cases, may be advisable. The large number of deaths simply reported as "bronchitis" or "nephritis" should not be placed under acute or chronic bronchitis or nephritis if the distinctive classification is to be maintained.

Age limits are undesirable, and as far as possible each title should designate a definite disease for which, when necessary, deaths at specified ages can be shown in the usual way. "Congenital" should be defined, and duration be considered in connection with "acute" and "chronic" forms of disease; also in relation to joint causes—a subject which can not be discussed in this paper.

Definite diseases of infants and of the aged should be compiled under the regular titles, and indefinite returns, e. g., "congenital debility" and "old age," should be placed under the class of ill defined.

Alternative methods of classification for deaths from external violence should be given, depending (1) upon the character of the violence and the means of injury, and (2) the character of the violence and the lesion. When the character of the violence (accidental, homicidal, suicidal, judicial, or unknown) can not be given, and there are legal difficulties in the way in some countries, then only the statement of means of injury or lesion will appear. Means of injury is the most important in general mortality and morbidity statistics, which should show the number of deaths from drowning, railway accidents and injuries, industrial accidents,

poisoning, etc., with as much precision and in as full detail as the returns will warrant. The classification by lesions, e. g., fractures, dislocations, wounds of specified location, etc., may be of special importance for hospital statistics, and may be given in addition to the regular statement of mode of injury. But no mixed system of classification should be employed.

The subdivisions of suicide should remain unchanged, unless it may be considered expedient to include the two least important numerically, "suicide by precipitation from a height" and "suicide by crushing" under "other suicides," thus abolishing

these unimportant titles.

It is desirable that a definite list of titles shall be prepared by the International Commission for each language. The process of translation from the French may give several apparently different forms. Thus we have, in the original translation of the Marine Hospital Service:

1. Typhoid fever (abdominal typhus).

2. Exanthematous typhus.

3. Recurrent fever.

* * *

39. Cancer and other malignant tumors of the buccal cavity.

In the U. S. Census reports:

Typhoid fever. Exanthematic typhus. Relapsing fever.

· · ·

* * *

Cancer of mouth.

In the Australian tabular list:

I. Typhoid fever.

2. Typhus.

3. Recurrent fever.

39. Cancer, etc., of the mouth.

In the Canadian Census:

Typhoid fever. (Abdominal typhus, enteric fever, mountain fever, dothienenteritis, typhomalarial fever.)

2. Exanthematic typhus. (Typhus fever.)

3. Recurrent fever. (Relapsing fever.)

 Cancer and other malignant tumors of the buccal cavity. (Epithelioma, smoker's cancer.)

All of these titles are supposed to be identical in contents, and there is no reason why they should not be precisely identical in form. It is important, moreover, that the international list numbers shall be used in all tables. By their aid comparisons can be made when the language is entirely unfamiliar. They are a guarantee, or should be a guarantee, that the inclusions under each title are absolutely those of the International Classification. Under the present arrangement, "27" means tuberculosis of lungs, including deaths reported simply as "tuberculosis," all the world over among nations using this system. I may urge the importance of this point because the U. S. Census reports do not now employ the list numbers in the printed tables. As soon as the re-

vised version is completed, however, they will be introduced and strictly maintained as a most useful part of the system. State and city registrars now enter them upon the transcripts made for the Bureau of the Census so that we may compare their assignments with those made by us, thus aiding in uniformity of methods of classification.

The titles themselves, as finally agreed upon for each language, should be in the most condensed form, without a long list of exceptions or inclusions; these are prescribed in the tabular list itself. A long title is frequently inconvenient when space is limited, and besides is usually incorrect from attempted over precision of statement. Thus title 46, "other tumors (tumors of the female genital organs excepted)," is misleading, because it excepts also a considerable number of tumors, or affections that are called "tumors," besides those of the female genital organs. These are (Australian Index): Tumor, aneurismal (81); tumor, bony (146); tumor, cerebral (74); tumor of bladder (123); tumor of liver (114); tumor of liver, hydatid (III); tumors of orbit (except cancer) (75); tumor of skull (146); tumor, parotid (100); tumor, phlegmonous (144); tumor, stercoral (108); tumor, varicose (83).

The list of terms included under each title should be prepared independently for each language and then correlated, as far as possible, remembering that some expressions in common use in one country may be replaced by others of entirely different character in another. The mere translation of an extended French list is entirely inadequate and brings about some very curious results. Thus the terms included under title 1, typhoid fever, are as follows (Australian tabular list):

1. Typhoid fever.

This heading includes—Dothinenteritis [Dothinenteritis]; fever, adynamic; fever, ataxic; fever, continued; fever, enteric; fever, mucous; fever, typhoid; typhus, abdominal.

Of the eight terms given as proper to be compiled under typhoid fever, the first three and also the term "mucous fever" practically never occur in re-turns in the United States or, presumably, in other English speaking countries. The most common, dothienenteritis, has not been received more than once or twice out of over 5,000,000 transcripts of deaths received by the Bureau of the Census since 1900. It is so obsolete as not to be found in recent standard medical dictionaries, although dothiénentérie may or may not be common present usage in France. "Ataxic" and "adynamic" and "mucous" fevers very fortunately have never been English medical terms at all, except as they have been translated from the French fièvre ataxique or adynamique or muqueuse. We have enough indefinite ways of saying "typhoid fever" without manufacturing artificial ones, and it is quite supposable that a physician seeing such expressions contained in an official list might be led to employ some of them. "Abdominal typhus," although even placed in parenthesis in the title itself, practically never occurs upon certificates; and the Latin form "typhus ab-

tf Ducland I to the mild point to the field of the fire, 1906

dominalis" is rare, and when it occurs is usually

written by German speaking physicians.

On the other hand we find that many terms that are regarded by some authorities as synonymous of typhoid fever are omitted. Thus Tyson (Practice of Medicine, 1906) lists the following as synonyms of typhoid fever: Typhus abdominalis; enteric fever; pythogenic fever [obsolete]; gastroenteric fever; nervous fever; autumnal fever; slow nervous fever. Some of the distinct terms actually contained in the transcripts received at the Census Office are: Abortive typhoid; ambulant typhoid; cerebral typhoid; enteromesenteric fever; typhoenteritis; typhobilious fever; typhogastric fever; typhoid endocarditis; typhoid ulcer; typhomalaria; typhoperitonitis; and, recently, paratyphoid fever. Provision must be made in a list that is to be generally used in registration offices, and sometimes not under medical direction, for the exact assignment of even the most irregular and indefinite terms, so that the limited list confined to the terms of the French index is quite inadequate.

The foregoing criticisms may be considered, upon the whole, to be of no very startling character or such as the ordinary work of revision will not readily eliminate. We are probably not yet ready for any radical rearrangement of titles according to the origin of disease; science is changing too rapidly just now for an ideal grouping. And we can maintain the integrity of the titles standing for specific diseases just as well with one skeleton to hang them on as another. Change or alteration of any kind is earnestly to be deprecated unless absolutely necessary, for it produces "faults" in our series of statistics as earthquakes do in the geological strata. "And all the king's horses, and all the king's men" can not put them together again years afterward when consecutive data may be most important. So iet us revise as much as may be necessary, and no more; giving the benefit of the doubt always to the present accepted method rather than to any pro-

posed change of uncertain value.

I have not condemned the International Classification for not being what it never for an instant undertook to be, namely, a nomenclature of diseases. Many physicians, and even some registrars, have confounded its nature and purpose with that of the "Nomenclature of Diseases" drawn up by the Royal College of Physicians of London, and which I heartily wish were in general use among physicians in the United States at the present time in the entire absence of any other accepted source of authority in the use of medical terms." The General Committee of the American Medical Association is preparing a report upon this nomenclature, and I hope it may become the basis for a complete International Nomenclature of Diseases, which may be prescribed for official use in hospitals and government services and recommended to physicians generally.

Specific Criticisms and Recommendations.—This paper is already too long, and I have touched upon some specific points requiring improvement in the examples under typhoid fever. It is desirable that

suggestions be sent in to the chairman of the section committee which is concerned with the question of classification, and so far as they touch individual titles, they might be submitted in something like the following form, each distinct suggestion being preferably made upon a separate slip or card of postal card size:

Reference should first be made to the title of the International Classification in its present form which it is desired to amend; the amendment stated, and disposition as regards any other title concerned; reason for change; and signature of proposer or name of office recommending change, with date. All of the new terms included in the Manual of International Classification published by the Bureau of the Census in 1902 may be considered as individual recommendation for inclusion under the titles to which they are referred. Also all of the new subdivisions established in the Manual and employed in the Mortality Statistics of the United States are submitted to the International Commission for consideration. A considerable number of new terms received since the compilation of the Manual will also be included, and it is desirable that each registration office likewise submit its suggestions.

Doctor Bertillon has requested that the recommendations be received by November 1, 1908, and it is the desire of the General Committee and of the Bureau of the Census to have the American suggestions in hand as soon as possible after October I, 1908, so that they may be properly arranged, and transmitted. The reason why Doctor Bertillon desires that suggestions be sent in by November I is that it is necessary to classify them, arrange in proper order, and publish them in a special pamphlet for the use of the International Commission, as was done with the suggestions made in 1900. This involves much arduous labor and considerable expense, and I think we can best show how heartily we appreciate the devoted services rendered by Doctor Bertillon in the former revision, and the effective cooperation of the government of France, by heartily and promptly cooperating in the formulation and transmittal of our recommendations. Another decennial period, and I trust that the Third Decennial Revision will be held at Washington in 1919, and that by that time we shall have reached a practical basis of agreement so that England and Germany and all of the countries of the world may participate. No classification is so good but that it would be better if it were a system in universal use. and I believe that any reasonable concession in minor matters of form ought to be made if we can thereby secure general adoption of a single plan of tabulating causes of death and sickness throughout the world.

^{**}This printed for "His Majesty's Stationery Office," by Darling & Son, 34:40 Bacon street, London, E., and costs only one shilling. Some bookseller might do a service to American vital statistics by importing a number and advertising them for sale.

SOME PSYCHOLOGICAL TESTS MADE ON TUBERCULOSIS PATIENTS.

BY WALTER SANDS MILLS, A. B., M. D., New York,

Physician to the Tuberculosis Informary, Metropolitan Hospital, Department of Public Charities.

At Columbia University a very elaborate set of psychological tests has been devised for the examination of those who wish to be so examined. Each year many of the students are put through these tests, and the results are carefully recorded. While doing some of this work in the Columbia psychological laboratory in 1907, it occurred to me that it would be of interest to try some of the more simple tests on my patients at the Tuberculosis Infirmary of the Metropolitan Hospital. So far as I am aware this is the first series of tests of the kind that has ever been made.

The mental attitude of tuberculous patients presents nothing peculiar, except that quite often patients who are desperately and hopelessly ill think they are going to get well eventually. Patients less sick are very apt to be blue and despondent when they realize that they have tuberculosis. It used to be thought that the consumptive was a particularly sensitive and clever person. That possibly there was something about clever people that attracted the disease, or there was something about the disease that sharpened the sensibility of the sufferer. Neither idea is true. The consumptive is made of common clay-very common, sometimes. The disease is an unpleasant disease to have. As it progresses, the patient becomes sick, very sick, and is frequently an unpleasant person to care for.

I have immediate charge of the women's wards at the Tuberculosis Infirmary, which contain at any given moment from 110 to 140 patients. The institution receives none but charity patients, most of them far advanced in tuberculosis. Many of them are foreigners, most are but little educated. They are from the lower walks of life-some working women, others wives of working men, a few profes-

sional prostitutes.

When I began my investigations I thought it would be a very simple matter to get a large number of subjects. I soon found, however, that it was a difficult matter to select from my material persons who were intelligent enough to appreciate what was required of them, who could understand, read. and write English, and who were physically able to carry out the experiments. Altogether I was able to find just twenty-nine subjects during some six months, out of 243 patients treated, and all of these did not complete the series of tests. The patients selected were:

CASE I.—Girl, aged twenty years; born in United States; common school education; was a shop girl. History of ingrowing toenails; dated her troubles from an operation to relieve them. This was erroneous. During many months patient drank whiskey with one meal and beer with another. Transferred to the Metropolitan Hospital February 4, 1907, from another hospital, suffering from alcoholic neuritis, worse in the feet and legs. Had foot drop. Could not walk. Slight tuberculous lesion in chest.

CASE II.-Woman, aged thirty-nine; admitted, May 20 1907. Well to three weeks ago, when she caught cold. Had rheumatism, endocarditis, pleurisy, and tuberculosis. Patient very sick and tired and could not finish. The tests

made her nervous.

Case III.—Woman, aged twenty-eight years; admitted, November 23, 1906; brought in on a stretcher. Much bet-ter in May, 1907. Early stage.

CASE IV.—Woman, aged fifty-eight years; born in United States; admitted from Bellevue Hospital, March 26, 1907. Incipient tuberculosis.

Case V.—Woman, aged twenty-seven; readmitted, January 21, 1907. Fibroid tuberculosis. Very curious as-

CASE VI.—Woman, aged thirty-one; admitted July 31, 1906. Patient had been a prostitute for several years. Suffering from alcoholism, also from syphilis. Was unable to walk. Lower extremities paralyzed. Tuberculosis of the left lung. Patient had made slow but regular improvement, and at the end of May was apparently well except for lung condition.

 $C_{\Lambda SF}$ VII.—Woman, aged twenty-three years; admitted May 1, 1907. Tuberculosis left lung.

CASE VIII.-Woman, aged thirty-six; admitted, May 6, 1907; born in England.

CASE IX.—Woman, aged twenty-eight years; admitted, November 9, 1906. Tuberculosis. Patient complained of eyes hurting, so tests had to be discontinued.

Case X.—Woman, aged thirty years; admitted, April 13, 1907. Was inclined to be a little queer, mentally. Religious mania.

CASE XI.—Woman, aged forty-nine; admitted, September 10, 1906. Tuberculosis.

Case XII.-Woman, aged thirty-five; admitted, April 30, 1907. Very sick. Tuberculosis slight.

Case XIII.—Woman, aged twenty-eight; Norwegian; admitted, April 26, 1907. Tuberculosis, pleurisy.

CASE XIV.—This patient is not very sick now and is constantly improving. She had been in the hospital since October 29, 1906. Age thirty-six.

CASE XV.—Woman, aged thirty-one; entered hospital May 12, 1902, and had been there ever since. Had only one eye, the right. The other was lost when a child. This patient was quicker than the average. The loss of one eye did not appear to hamper her.

Case XVI.—Woman, aged twenty-eight; reentered hospital after an absence of three weeks, April 30, 1907. Was in hospital eighteen months the first time. Tuberculosis in active stage. During all tests with all patients my watch was open on the table. This was the first one to write "watch" against "time" in association.

CASE XVII.-Woman, aged forty-seven; admitted, April 10, 1907. In bad condition with tuberculosis.

CASE XVIII.—Girl, aged seventeen years; was admitted June 20, 1905. Had tuberculous hip disease as well as tuberculosis of lungs. Quite sick and suffered a great deal of pain at times.

Case XIX.—Woman, aged thirty-three; admitted, October 30, 1906. Had improved much.

Case XX.—Woman, aged fifty-one; admitted, May 18,

1907. Both lungs affected.

Case XXI.—Woman, aged thirty; admitted to hospital several months ago and operated upon for tumor of abdomen. This was followed by pneumonia. Now in tuber-culosis ward. Extremely nervous; seemed a little off

mentally. The association tests are meaningless.

CASE XXII.—Woman, aged twenty-eight; admitted,
March 18, 1907. Tuberculosis of lungs. Alcoholic neuritis.

In bad shape,

Free association. Patient exhausted and could go no further.

Case XXIII.—Woman, aged thirty; admitted, March 5, 1907. Tuberculosis.

Case XXIV.—Woman, aged thirty-two years; admitted, August 15, 1905. Lungs in bad shape.

Case XXV.—Woman, aged thirty-five; admitted. March

22, 1907.

CASE XXVI.—Woman, aged forty-one; admitted, November 23, 1906. Slight tuberculosis.

CASE XXVII.—Woman, aged forty-nine; admitted,

March 20, 1907.

CASE XXVIII.—Woman. aged thirty-five; admitted,

April 18, 1907. Tuberculosis, active stage.

Case XXIX.—Colored woman, aged twenty-three; admitted, March 29, 1907. Had improved.

These twenty-nine subjects were all women suffering from pulmonary tuberculosis of varying severity. Some had other ailments as well. The subjects were all patients in the Tuberculosis Infirmary of the Metropolitan Hospital, Department of Public Charities, of the City of New York. The ages varied from seventeen to fifty-eight years. The average age was 33-7 years.

After consultation with Professor Woodworth, of the Psychological Department at Columbia University, ten simple tests were selected for the experiment. These were chosen because any person of average intelligence could do them. They required no special skill or intellectual training. A detailed description of each test, with the results of each

summarized, follows:

Test I. Perception of size:—The subject was given a piece of white paper and a pencil and directed to make a straight line the same length as a standard line on another piece of paper. The standard line was five centimetres long. The patient was not allowed to measure the standard, but was obliged to make her line as nearly like the original as possible, simply by estimating its size by the eye.

Each of the twenty-nine subjects made the test. Twenty made the line too long. One got hers the exact length. Eight made their lines too short. The

average length was 5.26 + cm.

Each subject was directed to erect a perpendicular to the first line at its centre, and of the same length. Twenty-eight did this. Six made the perpendicular longer than the original. One got both lines the same size—5.2 cm. Twenty-one got the perpendicular shorter than the original line. This is done by about the same percentage of normal persons. The average length of the perpendicular

was 4.55 + cm.

Test II. ** *Bsthesiometer:**—This test was made with one point, and with two points fixed respectively at 1.5, 2.0, 2.5 cm. distance. The instrument was touched lightly to the backs of the hands, both left and right, without permitting the subject to see whether one point or two were used. All twenty-nine subjects were thus tested, to see if they could tell by sense of touch the number of points touching them. Two got all points correct at all distances. Two others got all correct with right hand only. One other got all points correct with left hand only.

all shown and removed, asking her to write the list from memory in the same order. Two trials were given each subject. Twenty-eight were thus tested.

Only one succeeded in getting all the figures correct on the first trial. Two got all correct on the second trial. Three got all wrong on both trials. One other got all wrong on the second trial. Five got eight figures correct on the first trial; one got eight figures correct on the first trial; two got seven figures correct on the second trial. Two got seven figures correct on the first trial; two got seven figures correct on the first trial; Two got five figures correct on the first trial; one got five figures correct on the second trial. Two got four figures correct on the second trial, Six got three figures correct on the second trial. Six got three figures correct on the first trial; seven got three figures correct on the first trial; four got two figures correct on the first trial; four got two figures correct on the second trial. One got one figure correct on the second trial. Four had no second trial.

Eleven did better on the first trial. Nine did equally well on both trials. Five did better on the

second trial.

Test IV. A—Rate of perception test:—

One hundred A's arranged irregularly among five

One hundred A's arranged irregularly among five hundred letters in printed lines were checked off as rapidly as possible by the subject. Twenty-seven completed this test. The time varied from 75 to 300 seconds; the average time was 147.4 seconds. The average number of A's omitted was 14.6. Wisslar reported the average time of forty-two Barnard students as 91.2 seconds, with an average of three omissions. The poorer records of my subjects, I believe, to be due to their lack of mental training, and not altogether to the fact that they were sick.

Six subjects were evidently guessing and their statements were thrown out as unreliable.

Eleven altogether could feel two points at the 2.5 cm. distance at all times. Three altogether could feel two points at the 1.5 cm. distance.

All other tests were wrong with two points.

Test III. Visual memory:—For this test nine cards were used, each having on it one of the numerals, 1, 2, 3, 4, 5, 6, 7, 8, 9. The cards were shuffled to arrange them in irregular order. The test was made by placing the cards one on top of the other before the patient, and after they were

Test V. Steadiness of movement:-

This test consisted in making a line with a lead pencil between two parallel printed lines 2 mm. apart, and with twenty-eight right angles. The pencil mark was to be made continuous, and without touching the printed lines. The time was not recorded.

This test was made by twenty-five of the subjects. Three made no touches; three made one touch each; five made two touches each; two made three touches each; one made four touches; one made five touches; one made six touches; two made

seven touches each; two made eight touches each; one made eleven touches; one made twelve touches; one made eighteen touches; one made nineteen touches; and one was too bad to count. Of the twenty-four counted, the average number of touches made was 5.16 -.

Test VI. Accuracy of movement:-

This test was made with a 10 cm. square containing one hundred dots one centimetre apart. The patient touched each dot as quickly as possible with a pencil, the misses being counted afterwards.

Twenty-four did this test. The time varied from forty to one hundred and twenty seconds. The average time was 71.2 + seconds. One touched every dot in 75 seconds. Fifteen missed less than 10, one missed 70. The average number of misses was 17.1 +

Test VII. Speed of movement:-

The patient was required to place a dot in each one of one hundred I cm. squares as quickly as possible. Whenever a dot touched the side of a square or missed it altogether, it counted as an error.

Twenty-four did this test. The time varied from 35 to 115 seconds. The average time was 56.4+ seconds. Eleven made no errors. One made 14. The average number of errors was 2.4+.

Each of the preceding tests gives a much slower rate of speed than Wissler's averages for Barnard students. This I also believe to be due to lack of mental training on the part of my subjects.

Test VIII. Force:-This was taken with the dynamometer, two trials with each hand. The first test with the right hand varied from 12 to 40 kilogrammes; the second from 13 to 47. The averages were 25.1+ and 25.5 kilogrammes, respectively. The first test with the left hand varied from 10 to 50 kilogrammes, the second from 10 to 47. The averages were 25.6+ and 24+ plus, respectively.

The averages for healthy women were, right hand

34 kilogrammes, left hand 33 kilogrammes.

Test IX. Association test:—This test consisted in handing the patient a printed list of ten words and asking her to write down House as rapidly as possible opposite each word any other word that that word might Child suggest. The printed words were "House," "Tree," "Child," "Time," "Art," "London," "Napoleon," "Think," Time London "Red," "Enough." As a rule, associa-Napoleon tion was good, though the patients Think thought slowly. Another sign of defective mental training and inability, in Enough consequence, to think and write quickly.

The answers were:

Tree

Art

Red

Case I.—People, country, joy, .., .., of home, dress. . .

CASE II.—.., .., .., .., .., .., .., CASE III.—Home country, brother, work, picture, city, ..., thought, color, sufficient. CASE IV .- People, birds, toys, age, pic-

tures, Willis, war, Shakespeare, blood, this room.

CASE V.-Horse, three, chills, thyme, ate, long, nap, time, rude, eight.

CASE VI.-Hour, apple, little, the, words, going to, .., of, going home, hat, done.

CASE VII.—Inhabitant, apple, playful, hours, picture, people, foreigner, trouble, flower, work.

CASE VIII.-Home, children, work, true, Heart, London, .., .., ... Case IX.—..., .., .., .., .., ..,

CASE X.-Home, apple, children, too late, picture, England, Bonaparte, guess,

blue, plenty. CASE XI.-.., .., .., ..., ..., ..., ...,

CASE XII.—Home, country, sister, to spare, picture, a city, a great man, ...

CASE XIII.—Home, flower, baby, day, picture, big town, great man, sense, color,

CASE XIV.—To live in, fruitful, nature, good time, something, beautiful, large city, great, of owning large house, bright color, satisfied.

Case XV.—Home, nature, innocence, future, beauty, toggy weather, war, to bring back, passion, sufficient.

CASE XVI.-Home, nature, innocence, watch, beauty, foggy weather, .., taught, danger, frequency.

CASE XVII.—Work, up, nice, 4:20, do not know, was there once, great man, I think, color, sufficient. CASE XVIII.-Family, fruit, happy, work, statue, people,

a state, where going, color, goods.

CASE XIX.—Barn, woods, happy, rest, nice home, .., war, head, color, to let.

Case XX.-Home, summer, daughter, when I was happy, nice picture, large city, great man, I am sick, white and blue, all right.

CASE XXI.-Very good, right, anaught, concerned, proper, possess, necessary, protect, doctor.

city, hero, thought, color, finish.

· Case XXIV.—Home, plant, .., .., city, .., .., ... CASE XXV.-Horse, flowers, mother, thyme, picture,

ocean, nobleman, worry, color, plenty. CASE XXVI.-Home, fruit, mother, watch, ..., fog. great man, .., danger, sufficient.

CASE XXVII.—See, five, children, hour, how, city, home, how, blue, how.

CASE XXVIII.—Home, grows by nature, mother, leisure. a way to do anything, largest city, war, thought, anything red, plenty.

CASE XXIX.-Hotel, bud, my boy, here, picture, traveling, war, of myself, dress, here.

Test X. Retrospective memory:-At the end of each seance the patient was asked to draw a line from memory the same length as the standard line copied in the beginning, namely, 5 cm.

Twenty-five did this test. Seventeen made their lines too long; eight made their lines too short. Eight made their retrospective line shorter than the original, fourteen made it longer. Three made it

the same length.

Conclusions:-The tests seemed to me to show that previous mental training had much more to do with the results than did the physical condition. This was especially true as to the length of time consumed in performing each test. The patients were all intelligent enough to do what was expected of them, but it was entirely out of their accustomed routine, and hence they worked slowly. Performing the various tests was a distinct effort for most of them. The work started perspiration, and all left the examining room much exhausted.

As to speed, accuracy, sensibility, strength, in all the average was lower than for healthy persons. The patients were sick physically, most of them had had little education, and the results showed the

detrimental influence of both.

324 WEST EIGHTY-NINTH STREET.

THE AFTER TREATMENT OF A SERIES OF FORTY-FOUR LAPAROTOMIES.

> By Richard F. Woods, A. M., M. D., Philadelphia.

In all abdominal operations, the after treatment is of more importance than the preparatory treatment, and almost of as much importance as the operation itself. Carelessness or lack of judgment in this regard has caused a great deal of suffering and has lost many lives.

The operation stands out clear and distinct, and is apt to engross entirely the mind of the surgeon. Its harassing complications, its dangerous involvements, are apt to overshadow the after treatment, which by comparison dwindles in importance after the main event has been performed. On this account the after treatment is too often apt to be left to the resident physician or nurse, and the directions are not carefully considered or distinctly imparted. The crisis of a great many serious cases does not occur on the operating table, but depends oftentimes on the careful and intelligent direction after the operation has been completed.

It is here that nursing is of the greatest importance, that rational, prudent methods, aiming at simplicity, and based on common sense, yield the great-

est amount of success.

The following points in the after treatment of laparotomy cases were deduced from a series of forty-four cases, all receiving the same after treat-

A radical departure was made in these cases in the treatment of the bowels after operation. Following out the suggestions made and the procedure practised by some operators, a laxative was not used immediately after operation. This had been our custom previously, and all cases so treated have not been included in this series.

The operations were as follows: Bilateral salpingooophorectomies, 21; unilateral salpingooophorectomies, 6; hysterectomies, 8; panhysterectomies, 1; appendectomies alone, 5; ventrosuspensions

alone, 3.

I have made this classification as simple as possible, placing the operation under its most important head, without regard to the complications involved. Thus there were many appendices removed in the operation for single and double salpingooophorec tomy, but I have only classified them under one The same thing applies to ventrosusoperation. pension, many being performed in the course of other operations which have not been classified as ventrosuspensions. These operations were performed by me at the Presbyterian Hospital in the service of Dr. Edwin Duer.

The anæsthetic was invariably ether. Before this series of cases we had tried beginning the anæsthetic with nitrous oxide with unfavorable results, the cyanosis and bronchorrhœa being more marked than when ether alone was used. This was due in part. I think, to the fact that the ether is suddenly begun in full doses when the patient is relaxed from the effects of the nitrous oxide and he does not have a chance to accommodate himself to the irritation of the ether and to take care of the accumulated mucus in the bronchial tubes. It was the custom in these cases to use drugs only when the occasion arose and never routinely. A drug that is not required certainly does no good and may do some harm. desire to do something in a serious case, the impatience of delay, the appeasement of a conscience in leaving nothing undone, is often the cause of unwarranted over dosing and even poisoning. Large doses of stimulants flogging a tired heart often make it falter and break. Idiosyncrasies to certain drugs may cause a great deal of trouble. For this very reason, the use of morphine given when the patient was on the operating table was discontinued in this series of cases, one patient's respiration gradually sinking to seven on this account. It also seemed to us that nausea was more marked in the cases where morphine was given during the operation. Our custom in the use of this drug after operation was based entirely upon the suffering of the patients. Invariably, if there was much pain it was given, generally in doses of gr. 1/0, repeated in three hours if necessary. We have thought that the benefit derived from this drug so eclipsed the harm that it might cause that we have used it very often. The picture of the tossing, moaning, pain racked patient, so common in the old days when morphine was feared, has given way to the quiet calm, the indication of suffering easily borne.

It was generally given by hypodermic injection, as it seemed to have more mental effect and to give more relief than when administered by suppository. Morphine should never be used unless necessary, however it seems unjustifiable to withhold it from

patients who are suffering.

The stimulants used in some cases in this series that came off the table in bad condition were strychnine, alcohol, digitalis, and occasionally nitroglycerin. Strychnine in doses never larger than gr. 1/30, and seldom oftener than every three hours; digitalis, gtts v, generally every third hour; alcohol in the form of whiskey in half ounce doses, third or fourth hour, and nitroglycerin, grs. 0.01, third or fourth hour. Caffeine was used sometimes in the form of coffee enema when there had been no intestinal injury during operation. Atropine was used occasionally in severe sweating or in bronchorrheea, and in two cases where there was some distention we thought that it would encourage peristalsis.

We found that the average laparotomy did not need much medication after operation, but that strychnine nitrate, gr. 1/30, t. i. d., the day before

was an advantage.

The routine practice of giving calomel, which has been our practice hitherto, was abandoned in this series of cases. We found that this was a distinct advantage. Patients do better when they are not stirred up and weakened by severe purgation. Their first night was certainly more comfortable. The pain and distention much less, and the nausea and vomiting not so marked.

In the preparation of the patient for an operation oftentimes they are purged too effectually, the guts are wrung out instead of being effectually moved, and after being weakened by this method of procedure, to follow it up with drastic doses of calomel twelve or fifteen hours after a prolonged and serious operation is too exhausting. In these cases a simple enema of soap and water, with a little glycerin in it, was given twenty four hours after operation; if this was not effectual it was repeated in three hours, and on the bowels still resisting a compound enema was given in three hours. This consists of the following:

| 1: | Mag sulph, oz ii: |
|----|--------------------|
| | Oil of turpentine, |
| | Glycerin,oz. iii; |
| | Water,oz. iv. |

Water was given after the operation, two or three ounces, hot, every two or three hours. This was increased gradually, according to the tolerance of the If vomiting continued this was withdrawn entirely. In such cases salt solution enemas were used, a pint every four hours until vomiting ceased. Occasionally when vomiting was severe recourse was had to the stomach tube, and sometimes we thought that it did good. As a general rule. however, this mode of procedure involves too much discomfort to the patient, and the good derived does not compensate for the trouble involved. The general custom which we followed of giving large draughts of water twenty-four hours before operation, is one of the best methods of preventing discomfort from thirst after operation, and it also has an excellent effect upon the kidneys, and the scanty. high colored, concentrated urine is very seldom present if this method of preliminary water drinking is insisted.

In septic cases, the Fowler position was used with continuous rectal irrigation with salt solution such as Murphy directs. In cases where shock was pronunced, either from hæmorhage, sepsis, prolonged operation, or all of these conditions combined, hypodermoclysis was used or intravenous transfusion. We observed none of the nervous symptoms that have been reported after intravenous transfusion.

As a general rule nourishment was not given until the bowels had moved. If given too soon or in too large quantities, it is not absorbed, ferments, and creates digestive disturbances and distention. Buttermilk in small quantities was used by us, and was found to be enjoyed and tolerated. This was varied with broths. Milk was never used, as it certainly seemed to cause much more flatulence than any other form of nourishment. In six or seven days, if everything went well, we allowed semisolid food: Jellies, milk toast, and egg. In ten days: Vegetables, and meat occasionally.

It was made of particular importance that rest should be enforced. The worry and irritation caused by solicitous friends and relatives should be avoided by not allowing patients to be seen until they are convalescent. The majority of the patients with no complications were kept in bed for two weeks; others, where hysterectomies had been performed, or after operations for bad pelvic conditions where drainage was used, were kept in bed for three weeks at least. In our opinion it was much better to err on the safe side. The danger of embolism, phlebitis, and hernia is so great in patients who leave their beds early that undue baste is to be deplored, and nothing can be said in its favor compared to the great danger involved. A patient hurried out of the hospital apparently enhances the surgeon's ability for a quick cure and makes more room in the ward, but the patient repents and suffers at leisure at home.

There is a distinct period of secondary shock that occurs two or three months after operation. This postoperative condition (called by some postoperative neurasthenia) is certainly tempered by the proper proportion of rest and attention to convalescence.

The position of these patients was confined to the

back for twenty-four hours after the operation; after that, unless there was some serious objection, they were allowed to take any position they desired. Patients with ventrosuspension were kept on their backs for at least two weeks. A pillow under the back or knees in those cases where the backache was severe often gave considerable relief. These patients were catheterized every eight hours if they found it impossible to void their urine. Attempts were made with hot vaginal douches and warm applications on the abdomen, however, to encourage this if possible. In frequent urination, the catheter was passed as a rule to obviate the danger of distention with overflow.

A mild cystitis was present in three of these cases and occurred notwithstanding all regard to strict antiseptic precautions in performing catheterization, and impressed on our minds that all efforts should be used to induce patients to void their urine, and that the catheter is used as a general rule too routinely and that cystitis occurs more often than is commonly supposed. There were ten cases drained in this series, all for bad inflammatory conditions. These were all drained through the abdominal wound.

There is considerable question in our minds in regard to this method of drainage, and considering eveything the vaginal method seems the most satisfactory and the most practical. These cases were mostly drained with gauze enclosed in rubber tissue. Of this character of drain the condom makes a much better envelope than the rubber tissue. Taking everything into consideration, the rubber tube combined with gauze placed deep and low in the pelvis seemed to give the best results. We have never used glass tubes; they have no advantage over the rubber, but many disadvantages. There is remote danger of perforating the rectum; the remaining tract is much larger, and there is much more irritation. The danger of the gauze drain becoming dry and acting as a plug occurred in two cases, when its removal was followed by a quantity of turbid liquid which had been walled in by the gauze. In patients drained with gauze, the gauze was left in forty-eight hours, when it could be withdrawn easily and painlessly. Earlier attempts to remove gauze are generally accompanied by considerable difficulty. We had no stitch abscesses and of this series no deep sinuses from infected stitches followed drain-

Ligatures of silk were used to tie the uterine and ovarian arteries, iodine catgut for other bleeding points and for whipping over the peritonæum.

The attempt was made to regulate the habits and desires of these patients after they left the hospital. Realizing that the majority of the poorer classes return to arduous work far too soon, they were strongly advised in regard to feeding, work, habits, open air sleeping, and the systematic taking of tonics, while in the well to do a change of scene and air was advised to insure their convalescence.

In this series of patients all did well. There were no deaths, and the majority of the women were cured of their complaint.

FIFTEENTH AND SPRUCE STREETS.

APOPLEXY, ITS CAUSES AND TREATMENT.*

By John D. Bonnar, M. D., Buffalo, N. Y.

In approaching the discussion of this subject I am, at its outset, impressed with the vast range of influences and conditions, which, directly or indirectly, contribute to this morbid state, denominated apoplexy.

Its growing frequency, as a cause of death, gives it a place in the popular mind, of dread significance, portending either fatal or crippling consequences, that seldom come with such definite cer-

tainty from any other sickness.

The suddenness of the onset, with but meagre, if any, warning, is also a hindrance to such prophylaxis as might be adopted, if suspected; hence our efforts are focussed upon the incident, denominated the "apoplectic insult," which technically expresses the confusion and loss of consciousness, ending in coma. Inasmuch as coma may come from causes not purely apopletic in character it becomes of interest and value to distinguish or differentiate the causes. Alcoholism. uræmia, epilepsy, or concussion, may be mistaken for apoplexy. The history of inebriety, odor of breath, and absence of stertor and spasm, materially aid the early diagnosis, yet, where such inebriate habits may have led to atheroma of cerebral vessels, a combination of true apoplexy and alcoholism may exist—this is not frequent, yet significant and serious, where an apoplectic may hastily be denominated "a drunk" and sent to police station, instead of the hospital. Fortunately such error is rarely made by the physician, whose training precludes such possible blunder of the layman. Uræmia has also an history of kidney disease, and, while convulsive conditions are quite similar, the breath is said to have an odor of acetone, and the coma is less profound, while no paralysis is localized and the stertor is not so marked as in serious cases of apoplexy.

Epilepsy, while ushered in by convulsion and followed by coma, is also, in most cases, found in young subjects and has a history, while the reverse is the rule in apoplexy—exceptions but proving its truth.

The coma may last for a shorter or longer period, the seriousness being mostly proportional to its length. Where it lasts for several hours or a day, before some return of consciousness, the prognosis is grave, while, if the wave passes off in an hour or less, there are hopes of recovery, with more or less paralysis of muscles involved. Where the case was one of alcoholism, uraemia, or epilepsy, the paralysis passes off with the return to consciousness, while in apoplexy a defined area of loss of power and sometimes of sensation, is left after return to consciousness.

The clinical picture of such apoplectic cases is so familiar to all of us, I will not weary you with further delineation, but proceed to the discussion of its pathology.

The pathology of any disease must imply familiarity with the anatomical field of its invasion, coupled

Read before the Burale Academy of Medicine

with such contributary states, or conditions, as tend to its production. The brain, or encephalon, being the seat of its morbid invasion, we will briefly relate such main structural components as give ex-

pression to its symptoms.

After the ossification of the sutures and closure of its fontarelles, the cranium is an unyielding bony cneasement of spherical outline, containing the brain and its membranes, bloodvessels, and nerves. The brain is of soft and friable texture, composed of cerebrum and cerebellum connected through their peduncles with the pons and medulla—the cerebral expansion of the myelon.

These structures are enclosed by membranesdura mater, arachnoid, and pia mater. The first is thick and fibrous, is external, and serves as a periosteal lining for the cranium. The arachnoid is a serous membrane, lies between the dura and pia mater, and contains a small amount of serous fluid. The pia mater embraces the brain, and dips down between the convolutions, carrying the vascular supply to the textures of the brain. Cerebral fluid is found beneath these membranes and in the anterior and posterior subarachnoidean spaces, which communicate with each other across the crura and with the ventricles of the brain. This fluid acts as a cushion to lessen and equalize the shocks or jars, or sudden emotional or other influence, that tend to invade a portion of the encephalon, but, by this bumper medium, are distributed over much wider area of cerebral texture. Of next importance we mention the arterial supply, through the meningeal arteries supplying the surface, while the central and basilar parts of the brain receive their supply through the carotid and basilar and circle of Willis, which secures to the great nerve centres an excellent blood supply in normal state, while in abnormal, it supplies a most perfect way of meeting an emergency, created by occlusion of any part of the vascular arch—saving the citadel till the last; a Stoessel in command, in form of adjustment of pressure through venous and arterial currents hastening to close any vacuous spaces, which have arisen from sudden checking of the vascular supply, through one or other of the divisions of the arterial system; vascular congestion, throughout the encephalon, suddenly taking command and arresting the influx of the destructive blood forces, at the point of rupture or occlusion.

This cursory outline will now assist us in addressing our minds to such further anatomical truths, as will better fix the attention on the morbid chain of incidents, yet too limited to serve as basis from which to draw such conclusions as give practical command of the morbid centres, around which the issues of life and death must be met by the physician.

The gray matter of the brain is found distributed upon the surface of the convolutions, following their outlines in the sulci, thus giving greater area to this matter, we accept as the seat of intelligence. Gray matter is also found in the central parts of the brain, particularly at its basilar aspect, where the crura meet the lobes of the brain. The corpora striata, eptic thalami, corpora quadrigemina, and other well defined centres, from which the cerebral nerves take

their origin, give ample field for morbid action, peculiar to apoplexy. Also worthy of special mention are those folds of the pia mater, that extend into the ventricles of the brain, carrying arterial blood to their fine capillary network, in the choroid plexuses and velum interpositum. I mention these structures to draw your attention the better to what factors must engage our thought in dealing intelligently with clinical examples. In passing, I beg leave to remark, that the nerves of special sense are all provided with a deep and more superficial origin, which throws some light upon the fact that paralysis of nerves of special sense, as of sight, hearing, tasting, and smelling, are relatively infrequent, even where there is vast injury to motor and even sensory nerves of limbs.

The central branches of supply most frequently are the seat of hæmorrhage, particularly those given off from the middle cerebral, in the perforated spaces, which supply the striate and optic thalamic bodies—the lenticulostriate and lenticulothalamic arteries-the former, called by Charcot the artery of cerebral hæmorrhage-60 per cent. of all cerebal hæmorrhages occurring from one or other of these arteries. The bleeding may be into the substance or upon the surface of the brain-depending, no doubt, upon whether the rupture be within the capsule or superficial to the perforated space. The next structural feature of special interest is the motor track, beginning in the superficial convolutions of the anterior lobe of the cerebral hemispheres, in order of sequence of leg, arm, and face. A striking analogy is here shown between the brain and the myelon-the latter having also the motor centre in the anterior segment, or column of the cord-the sensory being posterior. So with the brain, the motor is in front-the centres of sensation being posterior and in the gray masses at its base and in the pons and medulla, the remaining gray tissues of the convolutions being seats of intellectual action. The anterior lobe presiding over individual character, the posterior and central over external fields of mental range-"associate centres" of cerebral action is a term used to designate such regions of the

Having now briefly reviewed the grand features of this dread disease, I will endeavor to make the outlines more definite, in order to get the clinical and pathological picture more clearly before our minds.

Symptoms suggesting its approach—premonitory—are rare, yet some prodroma, such as numbness or tingling in one side, and occasionally, choreic twitching—prehemiplegic, may occur; these may pass off without further disturbance, or may be followed by the more profound features of apoplexy, as vertigo, nausea and vomiting, and finally with loss of consciousness—"apoplectic insult"—suggesting congestion of the brain. Then follows still more profound evidence of pressure, preeminent, such as rapid pulse, showing evidence of acute general impoverishment of the supply of blood to the brain—"adiæmorrhysis cerebri" it is called.

We must now search for symptoms that will furnish a clue to the localization in the brain. While the patient is unconscious, our means are limited to

a few symptoms. The eves often afford suggestion of the nature of attack. Conjugate deviation, with nystagmus, transitory in character, suggest lesion on side towards which the eyes have turned and of a central location. If pupils are contracted, it suggests opium poison, but also suggests hæmorrhage into the pons or ventricles, at seat of origin of third nerve, lowering of temperature being more evidence of the latter than of opium, as a cause. At first the reflexes are practically nil, yet, as consciousness begins to return, there is more reflex in the unaffected side, then slight return in paralyzed limbs. On deep pressure, reflexes are found rather greater on that same side. If the eves twitch and rotate to one side, together with convulsive action, we may suspect cortical hamorrhage, when the pupils are not contracted, as is the case in hæmorrhage into pons or fourth ventricle, just cited.

When coma passes off, the case becomes better defined. Location of injury, or the focus, may be meningeal, cortical, or central. Meningeal, usually from fractured skull, or aneurysm, usually outside of the dura, or between it and the arachnoid. The next most frequent cause of meningeal hæmorrhage is rupture of large arteries—cerebral, in subarachnoid region, but an intracerebral hæmorrhage may burst into the meninges. There is a special form of hæmorrhage into the meninges in the new born, and is also found in some constitu-

tional diseases and fevers.

In ruptured aneurysms there may be a large quantity of blood at the base and extending into the cord, or upon the cortex, also, owing to the greater frequency of aneurysms in the cerebral arteries, the Sylvian fissures are often distended with blood.

Intracerebral hæmorrhage is most frequent in the vicinity of the corpora striata, particularly toward the outside of the lenticular nucleus, or into the internal capsule, or even into the lateral ventricles, or the insula. Hæmorrhages confined to the white semiovale are rare. Localized bleeding may occur in the crura or pons. Hæmorrhages in the cerebellum are not uncommon, arising from rupture of the superior cerebellar artery, it may be limited to the surface or rupture into fourth ventricle. Osler noticed two cases of sudden death in girls under twenty-five years from such cause.

Ventricular hæmorrhage is rarely primary—coming from the plexus or walls—while not so infrequent in early life, is more usually secondary. It may occur during birth. In adults it is caused almost always by rupture of artery in the neighbor-

hood of the caudate nucleus.

Causes of apoplexy may be classified as predisposing and exciting, or general and local, according to circumstances. The first include certain diseases and heredity due to such diseases. Syphilis, alcoholism, contracted kidneys, hypertrophy, and sclerosis—affecting the structure and valves, usually the miral, purpura, and scurvy leuchæmia, or pernicious anæmia. Sedentary habits and bowl torpor also predispose to this trouble. Such are chiefly the general causes also. Local causes may be cited as aneurysms—miliary and large—also endarteritis and diffuse softening of arterial walls; syphilis or alcoholism may be causes of such—leading to degenera-

tion and sclerosis, or even atheroma of coats of the

The apoplectic attack is usually caused by hæmorrhage from or embolism of an artery of the brain. Thrombi may occur as results of endarteritis, or sclerosis of walls.

Ingravescent apoplexy may come on slowly in the night, due to very slow leakage of blood. Small hæmorrhages in the territory of central arteries may cause hemiplegia, without loss of consciousness.

Course of the disease.—Early rigidity may develop, trophic changes now liable, such as sloughing ulcers of back and vesicles on the skin of that region; congestion of the base of lungs is said, by some, to be trophic nutritive deficiency. Marked hemianæsthesia results usually from lesion of the internal capsule, but, if of cortical origin, it is more usually limited to the face, arm, or leg, and is incomplete. In fact hemianæsthesia is rarely complete.

Disturbances of the special senses are not common, yet I have seen some well marked cases. The reason is attributable to the multiple origin, especially the superficial and the deep origin. There may be diminution of their power, or there may be, as Gowers thinks, quite usual hemianopia of homon-

omous kind, opposite to the side of lesion.

Recovery may quickly occur in the face, but in the hand and forearm is usually slow. Permanent contractures are associated with secondary descending sclerosis of the motor path, then reflexes are greatly increased. Atrophy is not a marked feature, but, when not due to secondary alterations in the gray matter of the horns of the ventricles, as in case cited by Charcot, it is probably due to lesions involving domain of the third ventricular branch of the Sylvian artery. It is most common in cortical lesions.

Prognosis.—Patients may recover from cortical apoplexy, unless very extensive—such usually following an injury. Infantile apoplexy may cause idiocy or spastic diplegia. When into coronaradiata and ventricles, it rapidly proves fatal; when intracapsular and following rupture of lenticular striate artery, it is persistent, but, if in retrolenticular space, it may be followed by hemianæsthesia and hemicorea. Bad symptoms are deepening coma.

rise in temperature and bed sores.

Embolism, as a cause of apoplexy, is due to heart disease, especially in recurring endocarditis, which attacks old sclerotic valves. Owing to the more direct course of the blood current, through the right carotid, the right middle cerebral artery is the more frequent seat of embolus, and is more frequent in women, owing to greater number of cases of mitral stenosis. When the central arteries are involved the softening, which is liable to follow, in the internal capsule, is commonly followed by permanent hemiplegia. When an embolus blocks the left middle cerebral artery, aphasia is a common result. If the apoplexy is in a young person, nonsyphilitic and not suffering from disease of the blood, embolism is very likely, particularly if there is coexisting cardiac disease.

Suldenness suggests embolus. Thrombosis may be due to embolus or, in absence of such, arise from

endarteritis, particularly syphilitic, with or without atheroma, or it may be due to aneurysms, great or small, which by their pressure, on the blood current, also, rarely are direct result of disease of blood. Embolus, following ligation of carotid, is mostly found in the middle cerebral or basilar artery.

Softening of limited areas sometimes arises from heart weakness and collapse. Apoplexy from thrombus is more gradual than is apoplexy from embous or hæmorrhage, and is preceded by headache, vertigo, tingling in fingers, embarrassed speech, loss of memory, incoherence, the paralysis beginning at one part, as hand, and extending gradually; the hemiplegia may be partial or variable. In small lesions, consciousness is retained. In syphilitic thrombus, paralysis is gradual, without loss of consciousness.

Blocking off of the internal carotids, within the skull, from thrombus or embolus, results usually in hemiplegia, coma, and death. The middle cerebral -the one usually involved-if plugged, before central arteries are given off, permanent hemiplegia usually follows from softening of internal capsule, but, if beyond this, it may be followed by hemiplegia, involving arm and face, or, if on the left side by aphasia also. If the thrombus is on the left side, in the supramarginal and central gyri, pure alexia and right hemiplegia are likely to follow, or, if it goes to temporal gyri, of left side, word deafness. Anterior cerebral artery anastomosis often prevents paralysis, but monoplegia of leg may result, hebetude and dullness also result. In cortical cases, anastomoses are so free that paralysis may practically entirely disappear in time.

If consciousness does not return in twenty-four hours, prognosis is grave in hæmorrhage, but not so poor in embolus, even where the time is longer. The outlook is better in any case, where conscious-

ness comes back, even for a short time.

Treatment.—Nature attempts to stem the ebbing tide at first, by increasing the intracerebral pressure, by equalizing the arterial pressure. Low position of the head is said to be best in embolism, while elevated is best in cases of hemorrhage. Cold packs at first to head are disapproved by some, on ground of lessening arterial pressure and thus increasing leakage, whereas cold is good, when feverish reaction appears. Views differ on these points.

Venesection is recommended in cases where there is marked rush of blood to the head, accompanied with headache, or in middle aged men, with arteriosclerosis, or accentuated aortic second sound and hypertrophied left ventricle. I personally like to draw off a small amount of blood in any case that is not too profound, if reached early, and even great depression of powers does not preclude its value in rendering relief, if done promptly and mildly. Where the pulse is small and of low tension, judgment must be exercised as to whether such is from pressure on the brain, or from heart weakness. If the latter, venesection is risky; but if the former it may save the day. Purgation is good, in hæmorrhages, but not in embolus or thrombus. Pressure on carotids is recommended.

Aconite, in fever of reaction, is good, also ice, if the head aches, to affected side. Medicine is not much advised, but I prefer to use potassium bromide

with ergot and a mild aperient. I recommend my patients, with prodromic symptoms of apoplexy, to take deep inspirations, so as to withdraw to the thorax the blood pressure bearing upon the brain. A little food in the stomach is also of value in diverting blood and nerve energy to the stomach, and has the virtue of ready use-the patients having been so warned. Wrap the swollen limbs in cotton or flannel. If the heart is feeble, give digitalis, ether, or ammonia. In syphilitic thrombosis in men, between twenty and forty years of age, give potassium iodide freely; if it is recent use hydrargyrum, by inunction. These are about the only cases of severity giving satisfaction from treatment, after early stage. In subdural hæmorrhages, operation is justifiable, but if in interior capsule or the central region of the brain, it is too dangerous. Nature, in such cases, is about the best agent. The hemiplegia that remains is hard to help.

Rubbing, after ten days, towards the body, is good; faradism after two to four weeks, massage, applied to muscles opposite paralyzed ones, even after contractions, electricity are still of some benefit.

Inform the patient's friends that, in complete hemiplegia, chances are slight, the leg may recover, but the hand rarely recovers finger movements. General health should be watched.

After middle life, there is liable to follow more or less mental weakness, irritability, and emotion-

alism.

After three months, without some marked im-

provement, there is not much hope.

If collateral circulation does not bring sufficient blood to the brain substance within forty-eight hours, the encephalomalacic focus is permanent. This fact makes such foci good objects for topical diagnosis of diseases of the brain.

As the disease is essentially in the nature of a last act, in the drama of many diseases, prophylaxis will greatly reduce emergencies and defer, or possibly dispel, the fatal blow from apoplexy.

REPAIR OF THE PERINÆUM.

By J. W. Henson, M. D., Richmond, Va.,

Professor of Surgical Anatomy, and Lectures in Principles of Surgery, University College of Medicine: Suggeon to the Virginia and the William Byrd Hospitals.

In this short paper the writer will not discuss any laceration occurring during parturition except that of the perinæum and adjacent parts of the vagina, nor will he enumerate the many distressing results of this injury. Every doctor of fair training and experience is familiar with the physical changes following it, as well as the suffering endured by the subject of such misfortune.

The prime object of this paper is to mention with emphasis, and briefly discuss two facts which seem to the writer chiefly responsible for the many failures following attempts at repair of the perinæum,

particularly in secondary operations.

It is true there are a number of other factors influencing results in this operation; but every careful surgeon is familiar with them, while the two, to be mentioned below, seem not to have attracted their share of attention, in spite of the fact that one of them is practically the key to the problem of repair of the perinæum.

The first (in importance) is imperfect comprehension, on the part of the operators, of the anatomy and physiology of the musculature of the perinæum. The second is the long interval, perhaps many years,

between the injury and the operation.

While it is granted that the transverse perineal muscles, superficial and deep, and the ischiopubic ligament are concerned in the support of the lower end of the vagina and should not be ignored, the structure of greatest importance, from the support it affords, is the levator ani muscle; it not only supports the rectum but the tendinous centre of the perinæum, the lower end of the vagina, and, indirectly, aids in the support of the uterus and bladder.

The writer has for years been struck with the apparent failure on the part of many writers to recognize all the functions of this muscle. With few exceptions the textbooks on general anatomy and gynæcology, in describing the structures in the perinæum, do not emphasize the importance of the levator ani in its relation to the female pelvic viscera.

The textbooks on anatomy give either an imperfect or incorrect description of the attachments of the anterior fibres of this muscle in the female, and many books on gynæcology are equally deficient. One writer of prominence demonstrates his belief in the importance of the levator ani, but strange to say, bases his belief on an incorrect theory as to its attachments.

Deaver, in his excellent Surgical Anatomy, gives the best description found in a textbook of the attachments of the anterior fibres in the female, and yet he does not give this connectively, but one has to piece it together, getting the parts from two widely separated paragraphs. He furnishes, however, in this book, a magnificent cut showing exactly what those attachments are, thus proving his faith. Weisse's Practical Anatomy has a cut showing the same thing equally as well.

The anterior fibres of the levator ani muscle arise from the posterior surface of the body of the os pubis and pass backward almost horizontally, inclining a little inward. Viewing both muscles, right and left, at the same time, the fibres behave as follows: The superficial fibres envelope the orifice of the vagina, and are inserted into the central tendon of the perineum. The deeper fibres envelop the lower part of the lateral and posterior walls of the

vagina, forming a sling.

It is stated by some writers that the lower end of the vagina is supported indirectly through the attachment of the levator ani to the rectum, thus pulling this viscus forward and pressing the vagina towards the pubis. This is true to an extent, but the chief support of the orifice and lower end of the vagina is that which is gotten directly through the anterior fibres of the levator ani, which being an elastic sling attached to the back of the rigid transverse bar in front, by drawing the perinæum and lower part of the floor of the vagina towards the pubis, not only act as a sphincter, but offer an ef-

fective, though resilient, support for the bladder and uterus.

It must be admitted, as stated before, that the attachment of the levator ani to the sides and lower end of the rectum aids in the support of the vagina, this aid being chiefly needed just above the vaginal attachment of the muscle. It is possible to have a central tear reaching from the fourchette through the attachment of the levator ani to the tendinous centre of the perinaum, without a subsequent rectocele or cystocele.

This is due to the fact that some of the anterior fibres of the levator ani pass behind the vagina, above the level of the central tendon, and are not torn necessarily when the latter is torn. Furthermore, the rectal attachment of the muscle lends its aid here.

When lateral tears occur in the vagina, they sometimes sever some of the rectal attachments of the levator ani. Such defects should be taken care of in operating. The relation of the levator ani to the perinæum and vagina in the normal condition can easily be demonstrated by physical examination.

With the thumb in the vagina and the index finger on the floor of the perinaum or through the anus, one can, by firm but continuous pressure, force the part back from the pubis and feel the tissue re-

lax and thin out between the fingers.

Irritate the perinæum or vagina with the finger nail, or ask the subject to contract the parts, and the ostium and lower end of the vagina will be drawn towards the pubis, and the tissue between the fingers will become thicker and firmer, which would not be the case if this pulling forward were due simply to the muscle fibres attached around the lower end of the rectum. Again, one can, with the index finger of each hand in the vagina and the thumbs outside, follow the vaginal levator loop from the pubic attachment on one side, across the perinæum to the pubic attachment on the opposite side.

Again, after laceration involving this loop, one can trace the muscular column of the anterior fibres of the levator ani backward to be lost in the tissues at the side of the lower end of the vagina.

When such a laceration occurs, the anterior fibres of the levator ani et vaginæ, as this muscle might well be called, have nothing to pull upon. They have lost their function. Like muscular tissue elsewhere, when inactive, the fibres atrophy. The longer the interval between the injury and the restoration of the attachment of the muscle, the fewer fibres are left. If any one needs a practical demonstration of this let him examine the recti abdominis after they have for years been widely separated and inactive from the presence of a ventral hernia. We see then that delay in repairing a laceration of the perinacum involving the musculature (and only such lacerations need repair) might well be reckoned seriously as a factor determining failure.

It should then be the duty of the obstetrician torepair immediately every laceration involving the muscular attachments, and it should be the duty of every physician, when an old, unrepaired tear, of the same class, presents itself to him, to use every argument to persuade the patient to consent to am operation without delay. As to which operation should be chosen only this point need be urged: Select the one which provides for the thorough

restoration of the muscular attachments.

The writer has for years used the flap splitting method by preference; first, because the muscles can be easily reached, and second, because no tissue is lost (the redundant tissue idea being merely a bugbear). The Mayos have improved this operation very much by the way the incision is made, and by the method pursued in placing the sutures.

The incision, as it is carried up on each side of the vaginal orifice, is inclined within the latter just enough for the anterior margin of the new perinæum. after the sutures are tied, to be a little back of the meatus so that upon micturition the urine is conducted off by the perinæum as a gutter, none of it trickling into the vagina, as it frequently does

after perineorrhaphy by other methods.

In introducing the sutures the needle is made to avoid puncturing the skin as it is passed in, and the mucous membrane as it is brought out, or vice versa. Thus the suture can take more of the muscular tissue in its grasp, and furthermore, it does not cut and get loose as sometimes happens when skin or

mucous membrane is caught.

The writer, believing that the sutures, even as introduced by the Mayos, will not restore to their attachments the fibres of the levator ani which pass behind the lower end of the vagina, above the central tendon of the perinæum, uses a figure of eight suture when introducing the second one counting from the lower end of the row of sutures, thus taking two bites at the muscle on each side with one

The same result could be accomplished perhaps better by placing a chromacized catgut suture to bring together the muscular fibres above the central

tendon before the other sutures are tied.

In conclusion it must be said that a detailed description of the operation has been purposely omitted, because such description would be tedious, and because the purpose of this paper is not to laud any particular operation, but to point out and insist that it is just as important to search for and thoroughly suture the several bands of the levator ani as it is, in case of complete laceration of the perinæum, to find and bring together the ends of the spincter ani.

215 BOULEVARD.

APOPLEXY IN THE CLASSIFICATION OF DISEASES.*

By Frank P. Foster, M. D., New York.

In this brief paper I shall deal only with cerebral apoplexy, or hæmorrhage into the brain, without paying any attention to "pulmonary apoplexy," a term which is passing into disuse apparently.

Cerebral apoplexy, or cerebral hæmorrhage, is included under diseases of the nervous system in the Manual of International Classification of Causes of

Death (the abridged translation used in the United States Census Office), in the Royal College of Physicians' Nomenclature of Diseases, in the Nomenclature of Diseases and Conditions employed in the case records of Bellevue and the Allied Hospitals of New York, and in all the textbooks of the practice of medicine with which I am acquainted. In special works on pathology it is treated of in connection with the circulatory system, though some of these works, according to the plan on which they are written, deal with it again under the diseases of the nervous system.

There are some physicians, it seems, who think that apoplexy ought to be classed with the vascular diseases in mortality returns and hence in certificates of death. It appears to me that this is a matter which may properly be considered by the Section on the Revision of the International Classification of the Causes of Death of the American Public Health Association. Nobody, I take it, will deny that apoplexy is essentially a disease of the bloodvessels or question the desirability of classifying diseases in accordance with their ætiology so far as such a classification does not conflict with practical considerations or with the general tenor of thought among practitioners of medicine.

Now, it seems to me that the general tendency of physicians is to think of apoplexy as pertaining to the brain. This is natural, and I fear it would be very difficult to break them of it. Is it desirable to make the attempt? To my mind, it is not; I think it would be not only impracticable, but also illogical. The present International Classification ranges malignant neoplasms by themselves, regardless of their situation; but it deals with benign tumors according to the part which they occupy. I think that this is correct. Apart from the displacement of fragments of bone, fractures of the skull owe their gravity to hæmorrhage from an intracranial vessel which has been torn in the injury, but would anybody dream of treating of such cases under the head of injuries of arteries? Tuberculous infection varies in its gravity according to the part involved, though the invading organism is the same in all instances. We dread the pulmonary and the meningeal manifestations much more than those of the spinal column, the joints, or the lymphatic glands, and in practice we do not associate them all together. It is the part affected that is of the greatest practical importance, and in the case of apoplexy

Whoever happens to be studying diseases of the vascular system from the statistical point of view may quite as readily obtain his data from returns of apoplexy as from those of degeneration of a cerebral artery, quite as he would have to do if he were dealing with some other disease of a particular organ, but one that owed its origin to vascular degeneration. We should commit an error, I think, if we were to demand that practitioners should substitute some other term for the time honored apo-

it is the fact that the brain is involved that is the

significant feature.

Our Renders' Discussions.

A SERIES OF PRIZE ESSAYS.

Questions for discussion in this department are announced at frequent intercals. So far as they have been decided upon, the further questions are as follows:

LXXVIII.—How do you treat acute coryza? (Closed

September 15, 1908.) LXXIX.—How do you treat sick headache? (Answers

due not later than October 15, 1908.)

LXXX.—How do you treat asphysia neonatorum.' (Answers due not later than November 16, 1908.)

Whoever answers one of these questions in the manner.

most satisfactory to the editors and their advisers will receive a prize of \$25. No importance whatever will be atreceive a prize of 325. Not important conductor will be disease solely on the value of the substance of the answer. It is requested (but not required) that the answers be short; if practicable, no one answer to contain more than six hundred words.

All persons will be entitled to compete for the prize, whether subscribers or not. This prize will not be awarded to any one person more than once within one year. Every answer must be accompanied by the writer's full name and address, both of which we must be at liberty to publish. All papers contributed become the property of the Journal. OUR READERS ARE ASKED TO SUGGEST TOPICS FOR DISCUSSION.

The prize of \$25 for the best essay submitted in answer to question LXXVII has been awarded to Dr. Maxwell S. Simpson, of Titusville, N. I., whose article appeared on

page 599.

PRIZE QUESTION LXXVII.

THE TREATMENT OF VARICOSE ULCER.

(Continued from page 602.)

Dr. Walter E. Hayes, of New York, writes:

The treatment of varicose ulcers should be both systemic and local. The body needs building up to enable it best to combat this pathological condition. The various predisposing diseases, such as scurvy, diabetes, rheumatism, gout, arteriosclerosis, or anæmia should receive special treatment, and the body put into a condition of greatest resistance with appropriate tonics. Tuberculosis and syphilis should be properly treated. Change of climate and rest are often valuable adjuncts to local treatment. The diet should be carefully regulated. Alcoholic drinks should be forbidden, and tea and coffee cut to a minimum amount. Salted meats, pork, shell fish, pastries and confections, pickles, sauces and condiments, cheese, and excess of starchy foods should be avoided as much as possible. The bowels should be carefully attended to, the salines being best in this condition. Stomachic tonics and digestives should be used as required.

If possible, the patient should be put to bed and the affected leg elevated. However, this is rarely done, because of the class of individuals in whom these ulcers occur. Though this is the ideal treatment, prompt response being made to local dressings, the ambulatory is the usual method of treatment. The patient usually comes to the physician because of the inflammation surrounding the ulcer or ulcers. Our first measures are to be directed to the reduction of this. Here moist dressings are to be used. A solution of lead acetate, 5 parts; alum. I part; to water, 100 parts; is efficient when applied on gauze and the leg kept constantly wet. Thiersch's solution, consisting of salicylic acid, I part; boric acid, 5 parts; to water, 500 parts; may also be used to advantage. Sometimes the heat and pain will be best relieved by the employment of a twenty per cent, ichthyol solution in liquid petrolatum or pure

After the inflammation has subsided, the ulcer must be thoroughly cleansed to promote the formation of healthy granulations. A five per cent. solution of formalin in tincture of green soap, rubbed gently into the sloughing area once or twice daily, is very effective. A one half to one per cent. solution of creolin may also be of service in cleansing the ulcers of the foul discharge escaping from them. Sometimes the destruction of sloughs is hastened by the use of the silver nitrate stick, which should be lightly but thoroughly applied over its entire The latter will also stimulate sluggish extent. Hydrogen peroxide, bichloride of mercury solution, I in 1000, or phenol solution 1 in 40 to 80, are very useful as washes prior to the application of some stimulating dressing. A solution of balsam of Peru, I part; in castor oil, 2 parts; except where the ulcer is very painful, gives very good results when applied directly to the ulcer and covered with absorbent cotton. Or a twenty per cent. solution of ichthyol in liquid petrolatum, or in lanolin as an ointment, applied once daily, is stimulating. If the surface of the ulcer is clean, but bathed in a serous discharge, powders may be used to dry it, such as aristol, xeroform, boric acid, iodoform, or zinc oxide. There are also others, but these are the most efficient. When the ulcer shows sluggishness in healing, the stick or ten per cent. solution of silver nitrate, or a solution of zinc or copper sulphate in the same strength, will, by setting up an inflammatory reaction, stimulate the growth of epithelium.

To relieve the venous stasis and congestion, and to provide a proper blood supply is absolutely necessary to a cure. The glycogelatin fixed dressing of Unna, consisting of gelatin and glycerin, aa 15 parts; zinc oxide, 30 parts; and water, 40 parts; should be heated on a water bath until it can be easily poured. A thick layer of this should then be applied to the whole eczematous area surrounding the ulcer and including it, if it be not too large, and covered with a thin layer of absorbent cotton. After it has become quite dry, which it does in a few minutes, the excess of cotton should be stripped off. This impermeable dressing relieves the itching which is at times so annoying, and exerts considerable pressure. It will be necessary to cut a fenestra in the dressing to treat the ulcer, if there is much discharge. Over this dressing of Unna's a muslin roller bandage applied will give added pressure, the bandage to be applied evenly and without wrinkles. Or a rubber bandage may be used to give even greater pressure. The roller bandage should be removed when the patient retires to rest. This glycogelatin dressing should last from two to three weeks, when a fresh one may be applied. After congestion has been relieved and the granulations are almost on a level with the surrounding skin, the edges of the ulcer should be lightly touched with silver nitrate stick, and strips of zinc oxide adhesive plaster, from one half to one inch in width, applied evenly around nearly the whole circumference of the leg. The

strips should overlap to the extent of about one third of their width and extend from one inch below the ulcer to one inch above. The plaster should be changed every few days. This pressure will continue the formation of new, healthy granulations and aid in the absorption of the thickened margins of the ulcer. Occasionally it may be necessary to make several small, lateral incisions of the edge, especially if the callosity is marked. Or a ring of wood or metal of the size of the outer edge of the ulcer may be tightly strapped on to make firm pressure. At times the base of the ulcer may become so firmly attached to the underlying tissue that measures will have to be taken to loosen its attachment and thus secure contraction of the ulcer.

If the varicosity of the neighboring veins is so marked that failure of healing is to be partly attributed to them, operative measures must be employed. Complete obliteration of the vein is to be desired. Thus the return of the blood from the lower extremity is accomplished by the deep veins, which are well supplied with valves and do not become varicose. Excision of the vein in six or eight places in its course is the best operation. Multiple ligature of the vein in thirty or forty places may be done. Or a circular incision may be made from four to six inches above the knee and a cuff of integument turned back for about two inches. All the superficial veins are then extirpated for one half to one and one half inches. This is very satisfactory usually. Trendelenburg's method of ligating the internal saphenous vein just below the point where it empties into the femoral has given good results.

In those ulcers which resist these measures and fail to heal, skin grafting or some sort of plastic operation should be done after the surface of the ulcer has been thoroughly cleaned and freshened. The transplantation of a piece of whole skin from a healthy surface and sutured down to the edges of the ulcer is the best method, because the tissues are less likely to undergo contraction and the appearance on healing is better. However, the small Thiersch grafts will grow much better. It is rarely possible to secure a flap of healthy skin nearby to use in a plastic operation, but may be tried.

Once the skin is healed, the patient should wear a snug fitting elastic stocking in order to support the veins, and thus prevent a subsequent breaking down and ulceration.

Dr. Paul P. Swett, of Hartford, Conn., states:

For purposes of treatment varicose ulcers may be divided into the following classes: 1, Recent ulcers: 2, old ulcers involving small areas of tissue; 3, old ulcers involving large areas.

The objects to be aimed at in the treatment of all these classes are the same, but the methods employed vary somewhat, and the above classification will be found convenient on this account.

Rational treatment involves the following essentials: I, Constitutional remedies. And 2, local treatment; a, correction of defective blood supply, which, by causing a passive congestion of the parts, is the fundamental cause of the trouble; b, reduction of inflammation in the ulcer and of the tissues in its neighborhood, which frequently present a cellulitis; c, cleansing of the ulcer; d, stimulation of healing process.

Constitutional treatment must be directed toward improvement in the patient's general health. Any organic disease must be appropriately treated, and as these patients are frequently met with among the overworked and poorly nourished classes, tonics, rest, generous diet, and such measures must be employed in order that full benefit may be derived from local treatment.

Keeping in mind these general considerations, the three classes of ulcers will be considered individually.

1. Recent ulcers. The passive congestion demands first attention and is best reduced by recumbent posture in bed, or, when this is out of the question or seems unnecessary by reason of the limited amount of congestion, by bandaging the leg from the toes to the knee with an ordinary stockinette horse bandage of sufficient length, 4 inches in width. The inflammation is reduced by a wet pack, consisting of several layers of gauze, soaked in a solution of alum acetate (5 parts lead acetate, and 1 part alum, to 100 parts water). Rubber dam may well be wrapped about the gauze and the whole encompassed by a horse bandage, as this saves frequent rewettings. Rest for the limb and the wet dressings must be continued till all the swelling and inflammation have subsided. Healthy granulations do not easily form unless the base of the ulcer is clean, and, as far as possible, sterile. Often, in recent ulcers, this treatment suffices to effect a cure; but when this does not occur the sloughs must be picked off, and their removal frequently hastened by touching them with a stick of silver nitrate. Having relieved the congestion, reduced the inflammation, and cleansed the ulcer, the patient is now allowed to leave the bed with the affected leg firmly bandaged, but if the healing process is not complete, as it frequently will be in these recent cases, it may be further stimulated by repeating the application of silver. Then apply around the margins of the ulcer a soothing zinc oxide ointment with three per cent. carbolic acid solution added. This dressing, as all the others, should be changed every twentyfour hours, though it may be allowed to remain for forty-eight when necessary. As soon as the reaction from the last application of silver has subsided, the ulcer may be dusted with boric acid powder, covered with a piece of rubber tissue, and the limb kept firmly bandaged. The application of a dry powder under the rubber tissue prevents the maceration of the granulations so frequently found where ointments are employed for long periods, and promotes the process of cicatrization.

As soon as the ulcer is completely healed, a silk elastic stocking is ordered, as this affords the readiest method of maintaining corrected circulation. In selected cases, however, removal of the affected veins is indicated, and this procedure should always be considered in younger subjects.

2. Old ulcers involving small areas of tissue. In this class the primary steps in treatment are the same as in class one, i. e., the reduction of congestion and of the cellulitis. It is, however, more essential that these patients be put to bed at once, and there is very little prospect that healing will occur without active stimulation. When the congestion and inflammation are reduced the patient

may be allowed to use the leg to a limited extent, if it is well supported by a horse bandage. Cleansing and sterilization are then promoted by a solution of creolin (one dram to a quart of water) applied as a wet pack. Healing is stimulated by daily applications to the base of the ulcer of gauze soaked in balsam of Peru and castor oil, with the zinc oxide and carbolic acid ointment applied around the margins. Usually, in this class, the edges of the ulcer are callous and thickened, and as soon as the granulations have reached the level of the edges, strapping with adhesive plaster strips, extending an inch above and an inch below the ulcer and reapplied preferably each day, forms the readiest method of completing the healing process. Occasionally the granulations become too prolific under this treatment, and they must be cut down with the silver stick, and the zinc oxide and carbolic acid ointment applied for a day or two till the reaction subsides, when the strappings may be continued.

3. Old ulcers involving large areas. The first three stages of treatment in this class are the same as class two. The essential difference lies in the methods which frequently are required to promote healing. The adhesive plaster strapping, if the granulations develop sufficiently, may be tried. If this fails, deep cross incisions of the base of the ulcer, extending through the edges, often promote healing by loosening the adherent base and permitting cicatrization to occur. If this method does not prove successful, skin grafting is the usual last

resort and is almost always successful.

Emphasis is laid on the importance of active, energetic, and intelligent treatment of this distressing affliction in the outset. Success depends largely upon the efficient carrying out of the first two stages—correction of blood supply and reduction of inflammation, and when this is not done the ulcer is simply unable to heal.

Dr. E. J. Leavitt, of Brooklyn, N. Y., observes:

In the treatment of varicose ulcer one must consider the patient, the circulation, and the ulcer from

the following viewpoints:

The state of the patient's general constitution must be carefully inquired into, since ulcers, as other wounds, will heal more readily in the healthy person. Also the social condition of the patient will have great bearing in the prognosis of the case, as well as in the choice of method of treatment as to time and expense.

Sluggish circulation being the chief ætiological factor, the cause of it must be ascertained. Valvular disease, abdominal tumors, pregnancy, tight garters, protracted standing—in other words, the usual causes of varicose veins—must be sought for and

overcome as far as practicable.

In many cases varicosities below the ulcer are secondary to chronic infected or traumatic ulcer, with its associated cedema and plastic or even cellular exudation, which may permeate all tissues from the cutis to the bone, in this manner choking off the venous and lymphatic stream.

In the usual cases of ulcer secondary to varicose veins attention must be directed to the veins. Among palliative measures may be mentioned cold bathing followed by friction of skin, exercise, of which bicy-

cling, since it brings all leg muscles into play, is probably the most beneficial form. The habit of resting one's legs in an elevated posture is more hygienic than elegant. Smoothly applied bandages or elastic stockings will afford material aid in maintaining an even circulation.

In more aggravated cases compression pads over the saphenous vein, or ligation of the vein, will be required. These procedures are most effective in cases due to weakened venous valves, in other cases excision of the veins is to be preferred. Weakened veins can be demonstrated by Trendelenburg's test, the limb is elevated and stroked centripetally, after the veins are emptied in this manner digital compression is applied over the saphenous vein and the limb lowered, the veins will then be seen to dilate slowly, but on relieving the compression they will instantly become distended to the greatest degree.

Cleanliness and relief of congestion must, above all, be the constant aim throughout the course of local treatment. All cases presenting themselves for treatment should undergo a thorough scrubbing with soap and hot water, followed by alcohol wash from knee to toe. Sloughs are then cleaned with hydrogen peroxide and scraped away with a sharp spoon if necessary, until healthy tissue is reached, this is then covered with iodoform powders; if there is pain and inflammation to be relieved, the limb is loosely bandaged with a few layers of gauze bandage and the patient is directed to rest in bed (this is very important to relieve congestion) and lead opium wash or a mixture of ichthyol and alum, āā one per cent.; lead acetate, five per cent.; constantly applied through the bandage. The ulcer should be cleaned daily, until discharges diminish, for which purpose hot saline or hydrogen peroxide washes are the best agents.

When the inflammation has subsided a dry dressing is substituted in the following manner: A piece of aseptic gauze is strapped over the ulcer to absorb the discharges, the zinc oxide strapping is then continued all over the congested parts; it may be made to cover the whole leg if necessary, leaving a narrow portion bare so as not to cut off all circulation; should there be an associated eczema the strapping is left off the eczematous parts, which are then covered with a powder of bismuth, twenty-five per cent.; alum, five per cent.; calomel, ten per cent. in starch; in either case, a piece of gauze and thick padding of nonabsorbent cotton is firmly but smoothly bandaged on, extending from knee to ankle, with muslin, flannel, rubber, or elastic bandage. The flannel bandage is more economic and satisfactory. The nonabsorbent cotton serves as a moist compress, and the bandaging equalizes circulation.

Under this treatment inflammation is reduced, congestion diminished, and ulcer cleaned in a surprisingly short time. The granulations assume healthy aspect, and the edges become a pale bluish color, indicating advancing epithelial covering. Pale and flabby granulations may be stimulated by pure ichthyol or better by light silver nitrate touches; hard, callous edges can be made to soften, and the spread of epithelium hastened by direct firm application of zinc oxide strapping over the ulcer. In obstinate cases the patient is directed to apply hot

boric acid compresses for several hours before presenting himself for treatment; this is followed at the office by dropping of water as hot as can be borne from a level higher than the patient's head onto the ulcer, and treatment continued as described.

Ointments are never to be used on discharging surfaces; the fatty substance hinders absorption of

discharges.

Success will largely depend on the skill with which the strapping and bandaging are applied and the ability of the patient to comply with the physician's orders.

For extensive ulcers of long standing, not responding to judicious treatment, we have to resort to radical procedures, as by Thiersch's grafts or flap transportation from the other leg; the former is applicable to cleaning granulating ulcers only.

(To be concluded.)

Correspondence.

LETTER FROM LONDON

The Medical Inspection of Schools.—The Hampstead General Hospital.—Women and the Royal College of Surgeons.

London, September 8, 1908.

The large number of appointments that have recently been made in connection with the new Medical Inspection of School Children's Act have to some extent benefited the general practitioners. This act will give employment to a large number of medical men and women, and with the falling off in the number of students at the medical schools there will probably be felt some relief from the overcrowding that has existed in the ranks of the medical profession in England in recent years. A noticeable feature of these appointments is the large number of women who are candidates, and it is a matter for satisfaction that there has been very little tendency to lower the salaries of women inspectors as compared with those of men. The women doctors have supported their confrères very loyally in this respect, and have refused to accept salaries lower than those given to medical men for the same work. One difficulty in connection with these appointments is that very few medical men have had special experience in the examination of school children, and many have felt some diffidence in applying for these posts, owing to the special nature of the work to be done, as until quite recently the various medical teaching institutions have not provided special courses of instruction in the particular duties of these new posts. Various postgraduate institutions have now taken up this branch, and courses of lectures are being delivered on the medical inspection of school children, which deal with the special points to be observed in the systematic inspection of school children, and these should be of great use to the candidates for the new inspectorships.

A very curious situation has arisen with regard to the recent appointments at the Hampstead General Hospital This hospital had up to recently a staff consisting of some of the general practitioners of the neighborhood. Lately the staff was reorganized. The hospital committee applied to King Edward's Hospital Fund for assistance, and the Fund would grant this asistance only on condition that the staff should consist of consulting physicians and surgeons. In spite of the strong opposition of the general practitioners of the district, the board of the hospital adopted this change and advertised for physicians and surgeons. The British Medical Association supported the medical practitioners of the district in the attitude they had taken up, and, in accordance with their usual procedure in such cases, issued a warning notice in the columns of the British Medical Journal from week to week for several months. In spite of the warning notice, however, these appointments were accepted by some of the most prominent physicians and surgeons, including the chairman of the Council of the British Medical Association. It is not too much to say that the result of these elections came as a great surprise to most medical men, and though there probably has been some agreement as regards these appointments, it is very strange that at the time the warning notices were actually appearing in their official journal, the high officers of the British Medical Association applied for and accepted these appointments. Under such circumstances it appears that the warning notice is entirely futile, as it has been contemptuously ignored by the officers of the associa-

The question of the admission of women to the Royal College of Surgeons, which has been in abeyance during the vacation, will unavoidably come up for consideration again in the course of the next few weeks. At the forthcoming meeting of the Council, Mr. Clinton T. Dent, F. R. C. S., is going to move that steps be forthwith taken to admit women to the examinations of the Conjoint Board of the Royal Colleges of Surgeons and Physicians, and, further, that women be admitted to the examinations for the fellowship of the Royal College of Surgeons and for the license in dentistry. It will be remembered that the Comitia of the Royal College of Physicians recently passed a resolution in favor of admitting women to the college, but decided to take no definite step in the matter until the opinion of their surgical confrères was made known. The surgeons thought it right to obtain the opinion of the members and fellows of the college by taking a poll, and the result was that a majority of about 400 out of 10,000 voters decided adversely to the cause of the lady doctors. The Council then put off their final decision until after the summer vacation. There is no doubt that the result of the poll came as a great surprise to the bulk of the medical profession in London, it being confidently expected that a poll favorable to the women students would be declared. The Council of the Royal College of Surgeons is, of course, not bound to abide by the decision of the poll taken, and, considering that the medical and surgical degrees of several British universities and the diplomas of the Royal Colleges of Scotland and Ireland have long been granted to women, it may confidently be expected that it will not be long before the latter will be admitted to the examinations for the M. R. C. S. and L. R. C. P. At the same time it is not unlikely that the higher distinction of the fellowship of the Royal College of

Surgeons (F. R. C. S.) will be reserved for men

indefinitely.

It is only during the last thirty years or so that women have been able to obtain a British medical qualification with comparative ease, as, although Mrs. Garrett Anderson (at that time Miss Garrett) succeeded in obtaining a diploma in 1865, so much opposition was then raised to the admission of women to the medical profession, and so many obstacles were thrown in the way of the pioneers of the movement, that it was quite ten years before any further progress was made. In 1874 there were only two women whose names appeared on the Medical Register, those of Mrs. Garrett Anderson and Miss Elizabeth Blackwell. The latter had been practising in London some little time before the compilation of the first Medical Register, in 1858. and when she applied for her name to be included in the new official list (she was an M. D., United States of America) it was found that she could not be refused. Now there is a large medical school in London, connected with a well equipped hospital, The Royal Free Hospital, which is solely reserved for women students, and they can enter the profession with comparative ease.

Therapeutical Rotes.

Blepharitis.—In the *Therapeutic Gazette* for August, 1908, Brav formulates what he styles a rational method of treating blepharitis. After describing the various forms of the disease he touches on the different therapeutic measures employed to combat them. Blepharitis marginalis is usually accompanied by conjunctival inflammation, where it is best to employ a twenty-five per cent. solution of glycerite of tannin as a local application. A boric acid solution should also be prescribed for home use, as for example:

Massage of the lid is an important therapeutic measure. It is best applied by means of an ointment, and given by means of a series of gentle stroking movements made upon the closed lids with the index finger carried horizontally from the inner to the outer angle of the palpebral fissure. These movements should last from three to five minutes. The ointment of yellow oxide of mercury seems to have a favorable influence on the tissues of the lid. In some cases salicylic acid ointment exerts a more favorable action, especially when the blepharitis is accompanied by considerable itching. Brav prescribes the following simple combination:

| B | Salicylic ac | eid, | | | | gr. i; |
|----|--------------|------|-----------|------|------|------------|
| | Hydrous w | 1001 | fat, | | | 3i. |
| M. | Sig.: Apply | as | directed. | | | |

In some cases in which the itching is very marked he uses a tannic acid ointment of the following composition:

| B | Tannie neid. | gr. ii: | |
|----|--------------|-----------|--|
| | Petrolatum, | | |
| M. | Sig.: Use as | directed. | |

The use of cocaine is recommended where it is necessary to relieve the itching, and the following is prescribed by Brav [which, it may be remarked, is a wholly incompatible mixture from a theoretical standpoint]:

| 12 | Tannie acid gr. ii; | |
|----|--|--|
| | Cocaine hydrochloride, gr. i Petrolatum, 5ii. | |
| 11 | The state of the s | |

The Treatment of Chronic Gastritis.—Kahane recommends equal parts of compound tincture of cinchona and tincture of orange peel, fifteen to twenty drops of which are to be taken twice daily before eating, or the following:

Ointment for Psoriasis.—Danlos, cited in Journal de médecine de Paris for June 27, 1908, uses the following ointment in the treatment of psoriasis, eczema, etc.:

| P_i | Oil of cade, | | | ٠ | | | | | ٠ | | | -3 | iiss | . 9 |
|-------|---------------------|------|------|-------|------|------|--|--|-------|------|--|----|------|-----|
| | Talcum, Zinc oxide. | | | | | | | | | | | | - 1 | |
| M. | | | | | | | | | | | | | .11 | |

The Use of Paraffin in Hernia.—Dr. Charles C. Miller describes, in his Cure of Rupture by Para fin Injections, the paraffin compound as follows: White petrolatum, 3viii; paraffin, 5viii; melt together. This should be sterilized by standing the mixture in a covered container in a vessel of water which is also covered, and the water should be kept boiling for half an hour. With the paraffin should be boiled a number of test tubes; into each of these test tubes sufficient paraffin is poured for an injection; the test tube is then to be plugged with sterile cotton or cork. When the paraffin compound is to be used the test tube is heated so as to melt the paraffin. A softer mixture has the following composition: White petrolatum, 5viii; paraffin, 5ii. Melt together as in the preceding formula.

The Treatment of Hay Fever.—Menier (Bulletin général de thérapeutique, September 15, 1908) advises the inhalation of a solution of menthol in chloroform (I part of menthol in 25 parts of chloroform), or a spray of adrenalin solution, I in 2,000, to ward off an expected attack of hay fever.

The derangement of vision and eye trouble may be overcome by the instillation of one drop of either of the following solutions in each eye:

| R | Eserme sulphate. | (I) |
|-----|------------------|----------------|
| 71. | | (2) |
| М. | Distilled water. | 2" %: 51155 |

When the asthmatic symptoms predominate the following mixture is effective:

| R | Potassium bromide,5v; |
|----|--------------------------------|
| | Tincture of lobelia, |
| | Tincture of grindelia robusta, |
| | Camphorated tincture of opium, |
| | Syrup of orange peel, |
| M. | Decoction of senega, |

SUBSCRIPTION PRICE

Under Domestic Postage Rates, \$5; under Foreign Postage Rate, \$7; single copies, fifteen cents.

Remittances should be made by New York Exchange or post office or express money order payable to the A. R. Ellhott Publishing Co., or by registered mail, as the publishers are not responsible for money sent by unregistered mail.

Entered at the Post Office at New York and admitted for transportation through the mail as second class matter.

NEW YORK, SATURDAY, OCTOBER 3, 1908

THE SIXTH INTERNATIONAL CONGRESS ON TUBERCULOSIS.

The week now closing, the second of the three weeks devoted to the congress, has served for all that portion of the work which took the form of papers and discussions. It may be said of the communications that all of them were of value and that some of them were of phenomenal importance. There can be no doubt that the congress will prove to have been highly effective in diffusing our present knowledge of tuberculous disease among physicians and among the people. The experience and conclusions of many men of great capacity, assembled from various countries, have by its instrumentality been laid before us in a manner calculated to appeal more than is usually the case to the ordinary understanding of medical practitioners and of the educated portion of the general public.

The general management of the congress cannot be too highly commended. Perhaps its most notable feature was to be found in the printed abstracts of papers with which every member was provided at the time of registration. The complete set was printed in four different languages, English, French, German, and Spanish, and each member received the set printed in his native tongue. But this was not all; the abstracts had been prepared with unusual skill—not, we fancy, by the authors of the papers as a rule, for authors' abstracts are apt to be unbearably prolix. It is expected that the full to tof the proceedings will be ready for dis-

tribution in three months from now. If that expectation is fulfilled, its accomplishment may well be called extraordinary.

On the whole, it may be said that the place of meeting, the new National Museum, was well chosen. All the exhibits and all the section meetings were under one roof, and this arrangement was in pleasing contrast with the scattering of forces which is almost always a serious defect in the medical conventions held in this country. One did not need to subject himself to confusion or appreciable loss of time in getting from one section meeting to another. There was one drawback, to be sure; the building being unfinished and the work of construction still necessarily going on, the noise made by stonecutters and other workmen interfered materially with the efforts of some of the speakers to make themselves heard. In but few of the sections, however, was this distracting feature apparent.

Of course the attendance was larger than had been expected—almost 7,000. Such an occurrence is almost the regular thing. The badges, which were really of artistic device, gave out very early in the week, on the morning of the second day, and the best that the polite young women in attendance could do was to assure late comers that more badges had been ordered, and that they would receive theirs when the fresh supply came. While it is true that the usefulness of such a badge is present rather than prospective, he would be a captious man who should complain of such a small matter. An exceedingly ingenious expedient was hit upon for inducing persons to come early and stay longthat of assigning all the notable entertainments to Monday and Friday. The man who thought he could play touch and go with the congress was deservedly disappointed—that is to say, if he cared much for receptions and "smokers" and other such diversions - for there were none set down for Tuesday, Wednesday, or Thursday. There are so many persons who do care for such things that it will be strange if a similar device is not employed in connection with large gatherings yet to come. The general management of the congress, we repeat, was admirable.

THE PHILADELPHIA TUBERCULOSIS CONFERENCE.

The week now ending has, of course, been the most notable of the three weeks devoted to the International Congress on Tuberculosis, held in Washington, for it has been devoted to the reading and discussion of the formal papers presented in the

various sections. Many of the visitors from foreign countries and from distant parts of our own domain, however, betook themselves naturally to the scene of the congress some days in advance of the actual opening of the section work, and it was convenient and agreeable for numbers of them to stop in Philadelphia for a time on their way to Washington. They were thus enabled to take part in the important conference held in Philadelphia last week and give it a truly international character.

Philadelphia was already actively engaged in preparing for the celebration of the 225th anniversary of its founding, but the citizens were not so absorbed in this work that they could not spare time and energy for promoting the scientific efficiency of the conference held in Horticultural Hall, and the comfort and entertainment of their visitors. The conference was made a worthy introduction to the work of the Washington congress; more than that, it was in itself a notable event in the present world combat with tuberculous disease. It was well attended, and among those present were many whose names are prominent in the work. So general was the interest of Philadelphians in the occasion that the city in its corporate capacity entertained the participants in the conference at a formal dinner, which was well attended.

SCIENCE AND THE CHURCH.

The writer of history has a most difficult task. If he is content to take things on the surface, as many do, and is possessed of literary merit, his work finds favor with the people, and he often stamps the ideas of generations with his own notions, incorrect though they may be. To the more thorough student of the events of the past, due consideration of the manners and customs of a time makes him hesitate to measure previous generations by the notions of the present times, since he realizes that the customs of a people are in a constant state of flux, and that which receives approval at one time and in one place is met with disapproval in the same place some time later. The careful historian does not overlook the influence of group interests in the making of current opinions. Men banded together in groups produce group interests, which override individual interests and are in definite antagonism, open or concealed, to other interests. One of the most intricate and subtle of these antagonisms has been that of the struggle of religious groups, and it is no wonder to find that the moral weapons forged by the conflicting parties contain much untruth, calumny, and deceit.

It amazes many of us physicians of the twentieth

century to find that in the so called battle of religion and science so much uncalled for mental squinting has been present, and one reads the recent work of Dr. James J. Walsh, on The Popes and Science. with a definite feeling of sympathy that so powerful a group of men should have been so maligned. To the student of the customs of a time and of group sentiments it is perfectly intelligible that misrepresentation should have been thought a necessary weapon in the contest. Read from this philosophical attitude, the facts that Dr. Walsh presents are self evident, but for the mass-the usual unthinking mass—that adopts its notions, opinions, manners, and customs from those whose interest it is for such to be adopted, Dr. Walsh's championship of the popes in science will come as a surprise, if it is not received with a murmur of protest. The antagonism of the Church to science is a monumental myth; how it originated, the careful historian has not yet told us entirely. That its origin is to be found in the clashing of group interests there is little doubt. Dr. Walsh tells us about much of the humbug of some revered history.

Dr. Walsh shows from documents and the most recent authoritative histories of science, and especially of medicine, that instead of opposing it, the popes were as judicious and beneficent patrons of science as they were of art. He tells us that for seven centuries the papal physicians have been the greatest investigators and writers in medical science, and that no other set of men connected by any bond in history, even the medical faculty of any of the large universities, can compare with them in accomplishment. They include the father of modern surgery, the author of the first great dictionary of medicine, the author of the first treatise on gunshot wounds, the father of comparative anatomy, the discoverer of the circulation of blood in the lungs, the anticipator of Harvey in the discovery of the systemic circulation, and one of the great founders of modern clinical medicine, while the father of modern pathology was a personal friend of four popes and always stayed at the papal palace when he visited Rome. For over two centuries the greatest medical school of the world was the papal medical school at Rome. Its most important rival was at Bologna, which after 1512 was in the Papal States. Two other medical schools, those of Ferrara and Perugia, were also in the papal dominions. Until the beginning of the nineteenth century Italy was for the world the Mecca of graduate teaching in science, just as Germany has been for the last half century. History has no record of papal opposition to science, except the Galileo case. The great scientists of the Middle Ages were clergymen, and many of them were canonized as saints. All the talk about papal opposition to science has been pure assumption, founded on religious intolerance, bolstered up by the Galileo case. In spite of frequent assertions, there are no papal prohibitions of anatomy or chemistry, and above all, not of surgery, which developed very wonderfully in the Middle Ages.

We recommend this work to our readers, not in any sense desiring to further misunderstandings, but on the assumption that medical science is universal and should be free from the struggles of intolerance found in other fields of mental activity.

THE INCONVENIENCES OF CERTAIN MINOR ANTISEPTICS.

M. Salva Mercadé concludes his review of the untoward effects of various surgical antiseptics (Archives générales de médecine, July), to several features of which we have already referred, with a consideration of the occasional drawbacks in the use of hydrogen dioxide, boric acid, camphorated naphthol, bismuth subnitrate, potassium permanganate, and zinc chloride. In the case of hydrogen dioxide, or peroxide of hydrogen, as it is commonly called (eau oxygénée), the unpleasant effects hardly ever amount to more than inconveniences, and even these are not often encountered. We think, however, that the author goes too far when he accounts for them as invariably due to impurity of the product; or, rather, we may say that he does not specifically limit the statement (as he appears to have intended) to its agency in producing such irritative effects as erythema and ulceration. Sometimes the gas evolved proves more or less troublesome by reason of its distending action, as when it gives rise to emphysema. Of course the distention has nothing to do with the impurity of the preparation.

The distention resulting from the liberation of oxygen may be accompanied by great pain when the solution is injected into a cavity which is without a free outlet, such as many of the natural cavities of the body, or finds its way into pockets connected with the main cavity of a wound only by contracted communicating channels. This fact has led to the practical abandonment of the use of the solution for vesical irrigation, for example. It has been thought that local bacterial infection might be spread by this distending action in traumatic cases, and the author cites a case recorded by Coudrain (*Thèse de Paris*, 1904) in which secondary abscesses followed the use of the solution after an operation for disease of the vermiform appendix.

Ameng the trivial disadvantages of the employ

ment of hydrogen dioxide is its bleaching action, on account of which cosmetic requirements are inconsistent with its use in cases of wounds of hairy parts, unless the hair is already of the tint produced by the chemical. As to its alleged destructive action on catgut, the author cites Thiriar and Moreau as maintaining that it has no such effect unless it is contaminated with hydrochloric acid. Moreau (*Presse médicale belge*, liii, 1901, p. 99) seems to have attributed to this action the sudden occurrence of secondary hæmorrhage after an amputation of the thigh, though Mercadé does not expressly so state.

Injected into a bloodvessel, hydrogen dioxide, being at once decomposed, gives off bubbles of oxygen, and these, as Paul Bert supposed, may occasion fatal embolism. Although Laborde and Quinquaud are said to maintain that this danger may be avoided by giving the injection slowly, it seems to us that little reliance can be placed on that precaution; at all events, we should not recommend or even countenance the injection of a solution of hydrogen dioxide into the blood.

In the course of his remarks on boric acid, M. Mercadé mentions two fatal cases of poisoning with that agent used as an antiseptic. One was that of a patient whose pleural cavity was washed out with a five per cent. solution. In the other instance a man had been operated on for inguinal adenitis, and the wound stuffed with the powdered drug. On the third day diffuse erythema appeared, accompanied by cyanosis, sweating, vomiting, and coldness of the extremities. The temperature rose to about 102° F., and the patient died delirious. Subpericardial ecchymoses were found, also fatty degeneration of the liver and kidneys.

The toxicity of camphorated naphthol increases with the age of the preparation. It sometimes produces convulsions and pulmonary embolism. Five fatal cases from the use of camphorated naphthol have been collected by Guinard, which he reports.

Bismuth subnitrate, however harmless it may be when taken internally, has sometimes produced grave symptoms of poisoning when used as a dressing, such as a blackish sponginess and painfulness of the gums and violaceous spots scattered over the mucous membrane of the mouth. Constitutional symptoms often appear, consisting of vomiting, diarrhoa, hiccough, fever, and a dark coloration of the urine. Potassium permanganate rarely has an untoward effect unless it is used in excessive strength; it then acts as a caustic. Chloride of zinc, too, seldom gives rise to troublesome consequences unless it is employed in too strong solutions.

Changes of Address.—Dr. Seymour Basch, to 14 East Sixtieth Street, New York. Dr. Arthur A. Boyer, to 11 East Forty-eighth Street, New York.

Dr. E. A. Newton, to 1924 Chestnut Street, Philadelphia. New:on's summer address is 3 Victoria Strasse, Bad Nauheim, Germany

Dr. George I. McKelway, to 4813 Baltimore Avenue,

Philadelphia,

"Tag Day" for the Mountainside Hospital, Montclair, N. J., which was held on Saturday, September 20th, realized nearly \$3,000 for the hospital.

The Medical Department of the University of Pennsylvania inaugurated its one hundred and forty-third an-

nual session on Friday, September 25th

Cholera, Plague, and Smallpox in Japan.—During the year 1907 there were reported in Japan, exclusive of Formosa, 3,631 cases of cholera, with 2,525 deaths; 645 cases of plague, with 574 deaths; and 1,034 cases of small-pox, with 437 deaths

The Buffalo Academy of Medicine.- A special meeting of this academy will be held on Tuesday, October 27th, tor a further consideration of the question of incorpora-The committee appointed to arrange for a permanent home for the academy will also report at this meeting

The Medical Department of Vanderbilt University, Nashville, Tenn., opened its 1908-1909 session on September 16th. Chancellor Kirkland presided, and Dr. J. A. Witherspoon delivered the address. About two hundred

and fifty students were present.

Atlanta, Ga., College of Physicians and Surgeons. The opening exercises of the fifty-fourth session of this college were held on September 23d. Addresses were de-livered by Bishop Warren A. Candler, Judge Howard Van Epps, Dr. A. W. Calhoun, and Dr. V. S. Elkin, dean of the college

Malpractitioner Sentenced. - Dr. Charles Bushnell pleaded guilty to a charge of using the mails for the purpose of advertising the performance of criminal abortion and was sentenced to fifteen months' imprisonment in the Eastern Penitentiary, Philadelphia, on Monday, Septem-

ber 21st.

The Medical Department of Columbia University, New York, opened on September 24th, with about two hundred and fifty students present. The entering class numbers eighty-eight, which is thirteen more than lass year. Dr. Samuel W. Lambert, dean of the college, presided, and Dr. M. Allen Starr delivered the address.

The College of Physicians and Surgeons, Boston. opened its twenty-ninth session with one hundred and sixty-two students enrolled. Dr. T. D. Crothers, of Hartford, Conn., gave the opening address, in which he complimented the college on being the first in this country to provide for a regular course of lectures on psychotherapy. Local Epidemics.—Scarlet fever is epidemic in Allen-

There are about forty cases in the city, a place

of about 36,000 population.

There is a small epidemic of diphtheria in a portion of Cecil County, Md.

There are a few cases of smallpox in Cumberland Coun-

Vital Statistics of St. Louis, Mo.—During the month of July, 1908, there were reported to the Health Department 874 deaths from all causes, as against 1,074 for the month of July. 1907. Of the total number of deaths 270 were of children under five years of age. There were 61 still births. One thousand three hundred and sixty-five births were reported during the month, 1.294 white and 71 colored.

The New York Academy of Medicine .- A stated meeting of the academy was held on Thursday evening, October 1st. Dr. Le Grand N. Denslow read a paper on October 1st. Dr. Le Grand N. Denstow read a paper on Locomotor Ataxia, which included a report of thirty cases. Dr. M. Allen Starr and Dr. R. H. Cunningham opened the discussion on this paper. Dr. Joseph Collins and Dr. Charles G. Taylor presented a paper-entitled Changes Which Occur in the Spinal Cord in Certain Cases of Syphilitic Infection, which was illustrated with lantern slides. regular stated meeting of the academy for October 15th will not be held, the next stated nacting occurring on No. vember 5th.

Contagious Diseases in Chicago .- During the week ending September 19, 1908, there were 275 cases of transmissible diseases reported to the Department of Health, as follows: Diphtheria, 83 cases; scarlet fever, 79 cases; measles, 5 cases; whooping cough, 20 cases; typhoid fever, 52 cases; tuberculosis, 23 cases; diseases of minor importance, 1 cases

Southern Minnesota Medical Association.—The next meeting of this association will be held in Winona in August, 1909. At the annual meeting, which was held this year at Owatonna, the following officers were elected: President, Dr. Way, of Claremont; vice president, Dr. H. McGaughey, of Winona; secretary-treasurer,

Adams, of Elgin.

American Dermatological Association.-The annual American Dermatological Association—I he annual meeting of this association was held in Annapolis and Baltimore, Md., on September 24th, 25th, and 26th. Officers for the ensuing year were elected as follows: President, Dr. William Thomas Gilchrist, of Baltimore; vice president, Dr. William Allen Pusey, of Chicago; secretary and treasurer, Dr. Grover William Wende, of Buffalo. The next annual meeting of the association will be held in

Tuberculosis Medals.—The two gold medals which are given every three years by the International Conference on Tuberculosis for work done in advancing the fight against tuberculosis, have been awarded to Mr. Henry Phipps, of New York, and Dr. Frederick Althoff, of Berlin. Four silver medals were awarded to Dr. Bernhardt Frankel, of Berlin, Dr. C. Theodore Williams, of London, Dr. Lewis Landouzy, of Paris, and Dr. Emilio R. Coni,

of Buenos Avres.

The Woman's Medical College of Pennsylvania in-augurated its annual session on Wednesday, September 23d. The following changes were announced in the facul-ty: Dr. Harry C. Deaver to be professor of surgery, vice Dr. William L. Rodman, resigned; Dr. Harriet L. Hartley to be professor of clinical surgery; Dr. Theodore L. Le-Boutillier to be professor of pædiatrics, vice Dr. James H. McKee, resigned; Dr. Martha Tracy to be associate professor of chemistry.

The Massachusetts State Conference of Charities will be held in Fall River, October 20 to 22, 1908. The traveling tuberculosis exhibit of the Boston Association for the Relief and Control of Tuberculosis will be a feature of the conference, and arrangements are also being made with the Dental Hygiene Council of Massachusetts to have their dental and oral hygiene exhibit at the conference. ject of this exhibit is to establish dental hygiene in schools as a part of medical inspection.

The Colorado Medical Association .- At the annual The Colorado Medical Association.—At the annual meeting of this association, which was held recently in Steamboat Springs, the following officers were elected: President, Dr. D. H. Coover, of Denver; second vice president, Dr. D. H. Coover, of Denver; second vice president, Dr. C. H. Graves, of Canon City; fourth vice president, Dr. O. P. Chippey, of Saguache; secretary, Dr. Melville Black, of Denver; treasurer, Dr. George W. Miel, of Denver Denver

Civil Service Examinations.—The New York State Civil Service Commission will hold examinations on October 17, 1908. Among the positions for which the examinaoer 17, 1908. Annual the positions of White the tions will be held are the following: Assistant in clinical psychiatry, Pathological Institute, \$2,000; health officer. Town of Wells, Hamilton County; physician, sixth grade, State hospitals and institutions, \$900 and maintenance. last day for filing applications is October 10th. Full information and application forms can be obtained from Mr. Charles S. Fowler, chief examiner of the commission. Al-

The American Electrotherapeutic Association .the eighteenth annual meeting of this association, which was held in New York on September 22d, 23d, and 24th, was held in New York on September 22d, 23d, and 24th, the following officers were elected: President, Dr. Edward C. Titus, of New York; vice presidents, Dr. William D. McFec, of Haverhill, Mass., and Dr. Thomas D. Crothers, of Hartford, Conn.: secretary, Dr. J. W. Travell, of New York; treasurer, Dr. Richard Joseph Nunn, of Savannah, Ga.: executive council, Dr. Morris W. Brinkmann, of New York, Dr. Charles Rae Dickson, of Toronto, Canada, Dr. W. Benham Snow, of New York, Dr. Fred H. Morse, of Boston, Dr. Herbert Pitcher, of Haverhill, Mass., and Dr. Francis B. Bishop, of Washington, D. C. Personal.—Dr. F. J. Sheperd has been elected dean of the Medical Faculty of McGill University, Montreal, to succeed Dr. Thomas G. Roddick, who resigned recently. Dr. Harriet Hartley, of Philadelphia, has been advanced

from lecturer on surgery to clinical professor of surgery at the Woman's Medical College of Pennsylvania. Dr. Hartley is the first woman in the world to hold such an

Dr. Erminie H. Smallwood, of Chillicothe, Ohio, is reg-tered at the Philadelphia Polyclinic and College for istered at the

Graduates in Medicine.

The Wesley M. Carpenter Lecture will be delivered at the New York Academy of Medicine on Thursday, Ocat the New York Academy of Medicine on Thursday, October 8th, at 8:30 p. m., by Dr. Andres Martinez-Vargas, of Barcelona, Snain. The subject of the lecture is Tuberculosis of the Heart, Blood Vessels, and Lymphatics. It will be delivered in the Spanish language, but a pamphlet translation in English will be presented to every person in the audience, so that the lecturer can be clearly and easily followed. After the lecture a reception will be given by the president and fellows of the academy to the visiting members and delegates of the International Congress on Tuberculosis.

American Association of Obstetricians and Gynæcologists .- At the twenty-first annual meeting of this association, which was held in Baltimore, Md., on September 22d, 23d, and 24th, the following officers were elected elected; treasurer, Dr. X. O. Werder, of Pittsburgh, Pa., reelected. The next annual meeting will be held in Fort

Wayne, Ind., in September, 1909.

The Washington State Medical Association closed its nineteenth annual meeting of three days at the Keylor Grand Theatre, in Walla Walla, in the afternoon of Sep-Grand Theatre, in Walla Walla, in the afternoon of September 11th by deciding to join in a meeting with the associations of Oregon, Idaho, and British Columbia at Seattle in June, 1909. These officers were elected for the year: President, Dr. C. A. Smith, of Seattle; vice presidents, Dr. Y. C. Blalock, of Walla Walla, and Dr. W. D. Kilpatrick, of Bellingham; secretary, Dr. C. H. Thompson, of Seattle; treasurer, Dr. L. L. Love, of Tacoma; delegates to the American Medical Association, Dr. J. R. Wenn, of Tacoma; alternate, Dr. H. H. McCarthy, of Spokane.

Scientific Society Meetings in Philadelphia for the Week Ending October 10, 1908:

Monday, October 5th.—Philadelphia Academy of Surgery;

MONDAY, October 5th.—Philadelphia Academy of Surgery: Biological and Microscopical Section, Academy of Natural Sciences; West Philadelphia Medical Association; Northwestern Medical Society.

TUESDAY, October 6th.—Academy of Natural Sciences. WEDNESDAY, October 7th.—Academy of Natural Sciences. WEDNESDAY, October 7th.—College of Physicians: Association of Clinical Assistants of Wills Hospital.

THURSDAY, October 8th.—Pathological Society; Section Meeting, Franklin Institute.

FRIDAY, October 9th.—West Branch, Philadelphia County

Medical Society,

American Urological Association.-The New York American Urological Association.—The New York Academy of Medicine on Wednesday, September 23d. Dr. M. J. Echeverria reported a case of vesical calculi. Dr. Victor C. Pedersen demonstrated an irrigating sound for the dilatation of close strictures. Dr. Winfield Ayres reported a case of renal calculus. The paper of the evening was read by Dr. Follen Cabot, and was entitled Notes on Some Recent Interesting Cases of Prostatetomy. Recent Interesting Cases of Prostatectomy. Among those who took part in the discussion were Dr. Ramon Guiteras, Dr. J. Bentley Squier, and Dr. Martin W. Ware. The officers of the society are: Dr. James Pedersen, president; Dr. A. Ernest Gallant, vice-president; Dr. G. Morgan Muren, of Brooklyn, secretary; Dr. Thomas J. Carney.

The Eighth District Branch of the Medical Society of the State of New York, which comprises the medical societies of the counties of Eric, Niagara, Orleans, Genesee. Wyoming, Allegany, Cattaraugus, and Chautauqua, held its third annual meeting in Batavia, N. Y., on September 2nd The presidental address was delivered by Dr. E. E. Snow, of Batavia, and papers were presented by Tr. J. S. Wright, of Perry and Dr. T. H. McKee, Dr. De Lancey, of Rochester, and Dr. H. C. Booth, of Buffalo The following officers were elected for the ensuing year:

President, Dr. E. E. Snow, of Batavia; first vice president, Dr. Edward Munson, of Medina; second vice president, Dr. T. H. McKee, of Buffalo; secretary, Dr. Lee M. Francis, of Buffalo; treasurer, Dr. C. A. Wall, of Buffalo. The meeting next year will be held in Buffalo.

Infectious Diseases in New York:

We are indebted to the Bureau of Records of the De-partment of Health for the following statement of new cases and deaths reported for the two weeks ending September 26, 1908:

| | Sep | t. 19 - | -Sep | t. 25 |
|---------------------------|--------|---------|--------|---------|
| | Cases, | Deaths. | Cases. | Deaths. |
| Tuberculosis rulmonalis | 53 I | 140 | 530 | 172 |
| Diphtheria | 206 | 28 | ~55 | 2.4 |

The Health of Philadelphia.-During the week ending September 19, 1908, the following cases of transmissible diseases were reported to the Bureau of Health: Malarial fever, 2 cases, 0 deaths; typhoid fever, 79 cases, 13 deaths; scarlet fever, 28 cases, 2 deaths; chickenpox, 9 cases, 0 deaths; diphtheria, 54 cases, 4 deaths; measles, 13 cases, o deaths; whooping cough, 17 cases, 2 deaths; tuberculosis of the lungs, 77 cases, 41 deaths; pneumonia, 20 cases, 10 deaths; erysipolas, 2 cases, 1 death; pneumonia, 20 cases, 10 deaths; erysipolas, 2 cases, 1 death; puerperal fever, 6 cases, 4 deaths; cancer, 10 cases, 23 deaths. The following deaths were reported from other transmissible diseases: Tuberculosis, other than that of the lungs, 10 deaths: dysentery, I death; diarrhœa and enteritis, under two years of age, 41 deaths. The total deaths numbered 425, in an estimated population of 1,532,738, corresponding to an annual death rate of 14.40 in 1,000 of population. The total infant mortality was 191; 103 under one year of age, and 18 between one and two years of age. There were 49 still births; 22 males and 27 females.

The Mortality of Chicago.—During the week ending September 19, 1908 there were reported to the Department of Health of the City of Chicago 525 deaths from all causes, as compared with 558 for the previous week, and 618 for the corresponding period in 1907. The annual death rate in 1,000 of population was 12.64, as against a death rate of 15.29 for the corresponding week last year. Among children under five years of age there were 169 deaths, this number being 70 less than the number reported for the previous week, and 69 less than the number reported ed for the corresponding week in 1907. The principal causes of death were: Apoplexy, 13 deaths; Bright's disease, 31 deaths; bronchitis, 5 deaths; consumption, 77 deaths; cancer, 20 deaths; diphtheria, 6 deaths; heart diseases, 44 deaths; intestinal diseases, acute, 108 deaths: measles, 2 deaths; nervous diseases, 19 deaths; pneumonia. 28 deaths; scarlet fever, 6 deaths; suicide, 10 deaths; typhoid fever, 9 deaths; violence (other than suicide), 33 deaths; whooping cough all other causes, 144 deaths. Vital Statistics of New York.—During the week end-

ing September 19th, the total number of deaths reported to the Department of Health of the City of New York was 1,311. which, in an estimated population of 4.014,304. corresponds to an annual death rate of 15.46 in 1,000 of population. In the corresponding period in 1907 the annual death rate in 1,000 of nonulation was 16.73. In Manhattan the total deaths for the week numbered 667, corresponding to an annual death rate of 15.18 in 1,000 of population. In the Bronx there were 112 deaths, and a death rate of 17.84. In Brooklyn, there were 420 deaths, and a death rate of 14.68. In Queens, there were 81 deaths, and a death rate of 18.17; and in Richmond, there were 31 deaths, and a death rate of 21.09. Of the total number of deaths 425 were from diarrhoal diseases, 140 from pulmonary tuberculosis, 113 from pneumonia, from heart diseases, and 57 from contagious diseases. There were 480 deaths of children under five years of age, of which 208 were due to diarrhœal diseases. There were 84 violent deaths; 5 from homicide, 17 from suicide, and 62 from accidents. There were 117 still births. Five hundred dred and forty marriages and 2,192 births were reported during the week.

Cholera Abating.-Reports from St. Petersburg indicate that the cholera epidemic is decreasing in numbers and severity. The report issued for the municipal hospitals of the capital for the twenty-four hours ending noon, September 29th, gives 222 cases, 99 deaths, and 137 recoveries. Comparatively few new cases have been reported, and re-lief for the overcrowded hospitals of St. Petersburg appears to be in sight. According to press despatches, Surgeon General Rixey, of the United States Navy, makes light of the danger to the fleet from cholera in Manila. He is reported to have deprecated the worry caused to friends of those aboard the fleet by the circulation of rumors in the newspaper press regarding probable danger to the fleet from cholera at Manila. He is reported as saying that the hospital service is perfectly able to cope with cholera if it gets aboard ship. The extent of shore leave for sailors and officers, when the fleet arrives at Manila, will depend upon what the surgeons report to the admiral in command.

Meetings of Sections of the New York Academy of Medicine.—A meeting of the Section in Surgery was held on Friday evening, October 2d. The programme included the reports of a series of cases of operations under local anæsthesia by Dr. Henry H. M. Lyle and Dr. Winfield Scott Schley, and the following papers: The Com-bined Operation for Carcinoma of the Rectum, by Dr. Joseph A. Blake; Local Anæsthesia in Major Surgery with Especial Reference to Abdominal Work, by Dr. Winfield Scott Schley.

A meeting of the Section in Dermatology will be held on Tuesday, October 6th, at 8:15 p. m. The programme will consist of the presentation of patients, the reports of cases, and a general discussion.

The Section in Otology will meet on Friday evening, October 9th, at 8:15 o'clock. Dr. S. J. Kopetzky will report two cases of atypical sinus thrombosis, and the paper of the evening will be read by Dr. Robert Milligan on the Application of Dr. Arneth's Blood Charts in the Diagnosis of Obscure Mastoid. A general discussion will follow.

Society Meetings for the Coming Week:

MONDAY, October 5th.—German Medical Society of the City of New York; Utica, N. Y., Medical Library As-sociation (annual): Niagara Falls, N. Y., Academy of Medicine: Practitioners Cluo, Newark, N. J.; Hart-

Medicine; Practitioners' Cluo, Newark, N. J.; Hartford, Conn., Medical Society.

TUESDAY, October 6th.—New York Academy of Medicine (Section in Dermatology); New York Neurological Society; Buffalo Academy of Medicine (Section in Surgery); Ogdensburgh, N. Y., Medical Association; Syracuse, N. Y., Academy of Medicine; Hudson County, N. J., Medical Association (Jersey City); Medical Association of Troy, N. Y., and Vicinity; Hornellsville, N. Y., Medical and Surgical Association; Long Island, N. Y., Medical Society; Bridgeport, Conn., Medical Association. Medical Association.

Medical Association.

WENDESDAY, October 7th.—Society of Alumni of Bellevue Hospital, New York; Harlem Medical Association, New York; Elmira, N. Y., Academy of Medicine.

THURSDAY, October 8th.—New York Academy of Medicine (Section in Pædiatrics): Brooklyn Pathological Society; Blackwell Medical Society of Rochester, N. Y.; Jenkins Medical Association, Yonkers, N. Y.

FRIDAY, October 9th.—New York Academy of Medicine (Section in Otology): New York Society of Dermatology and Genitourinary Surgery; Eastern Medical Society of the City of New York: Saratoga Springs. N. Y., Medical Society.

SATURDAY, October 7th.—Therapeutic Club, New York.

The International Congress on Tuberculosis.—The medical sessions of the sixth triennial congress on tuber-culosis were opened at the New National Museum in Washington on September 28th, Secretary of the Treasurer Cortelyou acting as the personal representative of the President of the United States. The diplomatic corps, the officers of the congress, and the section presidents proceeded in a body to the stage in the auditorium of the museum. meeting was called to order by Dr. Lawrence F. Flick, who announced the election of the following honorary presidents: Dr. E. L. Trudeau, of Saranac Lake; Dr. Robert Koch, of Berlin: Dr. Louis Landouzy, of France, and Dr. C. Theodore Williams, of London. Mr. Cortelyou made a formal address of welcome on behalf of President Rosewells and was followed by the Decident of the dent Roosevelt, and was followed by the President of the Board of Commissioners of the District of Columbia, Mr. H. B. F. Macfarland. Dr. Robert Koch, of Berlin, responded to these addresses on behalf of the German delegates, similar responses being made by the following delegates: Dr. Fermin Rodriguez, Jr., of Argentina; Baron Hengelmüller von Hengevar, of Austria; Prof. Denys, of Belgium; Dr. F. Montizambert, of Canada; Dr. L. Sierra, of Chile; Dr. Juan J. Ulloa, of Costa Rica; Dr. Joaquin L. Jacobsen, of Cuba; Dr. Bernard Bang, of Denmark; Dr. C. W. Richardson, of Ecuador; Prof. Louis Landouzy, of France; Dr. Robert Koch, of Germany; Dr. Arthur Newsholme, of Great Britain; Dr. Lambros Coromilas, of Greece; Dr. Bongoschea, of Guatemala; Dr. Josselin de Long, of Holland; Dr. Antonio Stella, of Italy; Dr. Eduardo Liceaga, of Mexico; Dr. F. Harbitz, of Norway; Dr. Echeveria, of Panama; Dr. Ladislaw Detre, of Hungary; Dr. Sylvio Gurgel de Amaral, of Portugal; Dr. S. Trimescu. of Rumania; Dr. A. Wladimiroff, of Russia; Dr. Camilo Calleja, of Spain; the Hon. Conrad Cedrecanz, of Sweden; Dr. Frank Egger, of Switzerland, and Dr. Luis Melean Lafinur, of Uruguay.

This closed the general session, the remainder of the

This closed the general session, the remainder of the week, up to Saturday morning, being devoted to sectional meetings, supplemented by special lectures from distinguished delegates. A report of the proceedings of the sections will be found on page 667 of this number.

The International Conference on Tuberculosis is an

organization made up of representatives of national asso ciations for the study of tuberculosis from all parts of the The seventh session of this conference, which is world. The seventh session of this conference, which held yearly, was held in Philadelphia on Thursday, Friday, and Saturday, September 24th, 25th, and 26th, just preceding the session of the International Congress on Tuberculosis, held in Washington during the three weeks ending October 10th. The sessions of the conference were held in Horticultural Hall, Philadelphia, where the following subjects were discussed: Provision for Advanced Cases of Tuberculosis, by Dr. Biggs, of New York, and Dr. von Leube, of Würzburg. Prophylactic Measures in Tuberculosis, by Dr. Flick, of Philadelphia, and Dr. Raw, of Liverpool. Hygienic Requirements for Sanatoria, by Dr. Pannitz, of Barlin, and Dr. Lawrson Brown of Sanatoria. pool. Hygienic Requirements for Sanatoria, by Dr. Fannitz, of Berlin, and Dr. Lawrason Brown, of Saranac Lake, N. Y. Tuberculosis and Legal Rights, by Dr. Dixon, of Pennsylvania. Tuberculosis and Traffic, by Dr. Bonney, of Denver, and Dr. Baradat, of Cannes. Antituberculosis Education, by Dr. Farrand, of New York, Dr. Heron, of London, Dr. Calmette, of Lille, and Dr. Kirchner, of Berlin, and Crusade against Tubertulosis. culosis, by Dr. Pannwitz, of Berlin, and Miss Boardman, of Washington. Registration of Tuberculosis, by Dr. Walsh, of Philadelphia. The Danger of Tuberculosis Infection from Milk, and How to Prevent it, by Dr. Heymanns, of Ghent.

In addition, Professor Gotthold Pannwitz, of Berlin, secretary general of the International Association for the Study and Prevention of Tuberculosis, delivered a lecture on the evening of Wednesday, September 23d, under the auspices of the Hospital Association of Philadelphia, entitled Social Life and Tuberculosis. Dr. G. Theodore Williams, of London, delivered an address on The Evolution of the Treatment of Pulmonary Tuberculosis, on the evening of Thursday, September 24th, under the auspices of the Henry Phipps Institute for the Study, Prevention, and Treatment of Tuberculosis. Professor A. Calmette, of Lille, delivered an address on Saturday evening, September 26th, on The New Methods of Early Diagnosis of Tuberculosis, under the auspices of the Pennsylvania Society for the Study of Tuberculosis. Professor Calmette is the Director of the Institut Pasteur, of Lille. The secretary general of the International Association for the is the Director of the Institut Pasteur, of Lille. social features of the conference were complete. Henry Phipps Institute gave a reception to the foreign delegates on Thursday evening at the Bellevue-Stratford Hotel, after Dr. Williams's lecture. The Board of Trus-Hotel, after Dr. Williams's lecture. The Board of Trustees and the Faculty of the Jefferson Medical College gave a luncheon on Friday at 12:30 p. m., and the City of Philadelphia gave a banquet to the foreign delegates at the Bellevue-Stratford Hotel on Friday evening. On Saturday the Medico-Chirurgical College and Hospital gave a funcheon, and Mr. P. A. B. Widener gave a reception at the Widener Memorial Home at 5 o'clock, and supper was created at 6 500. At the Municipal Barquet on Friday. served at 6:30. At the Municipal Banquet, on served at 0:30. At the Municipal Barquet, on Friday evening, toasts were responded to by Dr. Abraham Jacobi, of New York. Professor von Leube, of Germany, Professor Calmette, of France, Dr. German Sims Woodhead, of England, and Professor Robert Koch, of Germany. Mayor Reyburn, Dr. L. F. Flick, Dr. Leonard Pearson, and Dr. Edgar Fahs Smith, of Philadelphia, also spoke.

 Some Points in the Applied Anatomy of the Tonsil, By HARRY A. BARNES.

4. Results in Adenoid and Tonsil Operations. A Study of a Series of Cases, By J. Payson Clark.

3. Some Points in the Applied Anatomy of the Tonsil.—Barnes reminds us that the faucial tonsil is a collection of lymphoid tissue lying on the superior constrictor fascia and between the faucial pillars. It differs from other collections of the same tissue found in various parts of the alimentary tract throughout its extent only in its size, its compactness, and in the arrangement of its lymph nodules about its crypts. There is no reason to believe that the function of the tonsil differs in any way from that of other similar lymphoid tissues. Therefore it may be removed in toto without appreciable loss to the economy. The author considers at present the crypts and the capsule. The calibre of the crypts varies at different depths. In a strictly normal tonsil the epithelial surfaces should lie in apposition throughout the whole course of the crypt. In the great majority of the tonsils that are removed, either on account of their size or for the relief of constitutional disturbances, marked pocketing of the crypts is found. These pockets may occur at any point; they are quite as apt to be deep as superficial. The junction of a branch crypt with the main trunk seems especially suited for their development. Any operation done on the tonsil for pathological conditions in crypts, and consequent toxic absorption from them, must have for its object their complete obliteration. This can be accomplished only by the complete removal of the tonsil. Operations in which the epithelial face only of the tonsil is cut away, or at best in which a very considerable part of the deeper portion is left, are likely to prove disappointing; the crypts remain, less deep it is true, perhaps in many cases more capable of drainage, but always possible sources of infection and toxic absorption. The capsule is thin, but tough. It is seldom over 0.5 mm. in thickness, except at points near the pillars. It is quite easily separated from the surrounding tissues at its upper half; at its inferior half it is much more adherent, since it is at this point that the larger vessels enter the tonsil. The structure of the capsule, its toughness, and the ease with which it may be separated from the underlying tissues, make the operation of dissection of the tonsil "in capsule" a very practical one. The dissection may be accomplished largely with blunt instruments after the initial incision through the mucous membrane, but at its lower half the capsule is usually so adherent as to require a cutting edge or a snare to complete the separation. The operation is incomparably neater and more thorough than any other, and is especially to be recommended in all cases in which the tonsil is superted to be the source of a systemic infection. The que tion of hæmorrlage after this operation is

important. A just estimate of this danger, however, cannot be given until the operation is more generally done. Anatomically, bleeding would seem to be more likely to occur, for the reason that the blood-vessels are severed in a tough fibrous tissue which allows them little chance for contraction or retraction. For this reason the author prefers the modified operation in which the more adherent part of the tonsil at the lower half of the capsule, at which point the vessels enter, is separated with a snare.

 The Technique, Rationale, and Indications,
 By WILLIAM LINCOLN BALLENGER.
- Restoration of the Conjunctival Cul-de-Sac for the Insertion of an Artificial Eye,
 By M. WIENER.
- 2. Developmental Deformities of the Crystalline Lens.-Collins, from his clinical and anatomical studies, makes the following suggestions concerning the treatment of congenital cataract: 1. To wait until a child is ten months old before operating. At an earlier stage the cornea is so small and the anterior chamber so shallow that the necessary instrumentation cannot be so satisfactorily carried out as in the more fully developed eye. Moreover, the amount of aqueous humor is so small that it does not suffice for the solution of the liberated lens substance. 2. In some cases in which the pupil is small and does not dilate well with atropine it is best to commence with an iridectomy. 3. In nearly all cases it is well to begin with a needling, for valuable information can be obtained by its means as to the thickness of the capsule and consistency of the lens should it fail to liberate much lens matter to the action of the aqueous. 4. If the cataract is a dense, white, anterior polar one, set in a ring of clear, or partially clear, lens substance, and apparently flattened from before backward (the so called disc shaped cataract), then an attempt should be made to separate the central white opacity with a needle and let it fall into the anterior chamber. Two needles are sometimes required to effect this. 5. If, on pricking the capsule, milky white fluid escapes into the anterior chamber (congenital Morgagnian cataract) it is well at once to evacuate this fluid, for fear of increased tension ensuing. 6. In some cases of congenital cataract the whole lens and capsule can be removed in a most satisfactory way by grasping it with forceps. Very often, however, such a procedure is followed by escape of vitreous. It is difficult to distinguish which cataracts can be safely dealt with in this manner. They generally seem to be complete cataracts with a tough capsule and lens matter of a gelatinous consistency. 7. If, after a needling and some absorption of liberated lens matter, a dense, tough, white, fibrous looking membrane remains, there is probably some atypical development of the anterior pert of the vitreous. An attempt had then best be

made forcibly to displace the membrane downward and backward out of the axis of vision.

4. Three Cases of Cerebellar Tumor. Operation in Two Cases.-Sinkler reports three such cases. Two patients were operated upon-one recovered, the other died; the first one was operated upon early, the other late. To save vision, an operation must be done at an early date. The third patient died suddenly, while in a fairly good condition,

before an operation was attempted. 5. Meatomastoid Operation in Chronic Mastoiditis.—Ballenger bases the rationale of the meatomastoid operation on the following principles: (a) The promotion of healthy granulation tissue and epidermatization of the walls of the mastoid wound. This is accomplished by making the surface of the bony wound smooth, and the proper adaptation of the plastic meatal skin flaps to it. (b) The establishment of ample drainage. This is accomplished by diverting the secretions from the mastoid antrum and cells through the window in the posterior wall of the meatus into the external auditory meatus and by passing blasts of air via the aditus ad antrum through the middle ear. If these conditions are established in properly selected cases of chronic mastoiditis, savs the author, the results will be as good as if the radical operation had been performed, and in one respect they will be much better, namely, the hearing will be much improved, often approaching normal. About the indications for operation, he remarks that it is too early to accurately forecast the same, as only an extended experience will afford the data for such a forecast. There are, however, certain broad principles on which the indications may be tentatively based. Based on the therapeutical indications, chronic mastoiditis may be divided into three classes, namely, I, those amenable to nonoperative treatment, or to surgical treatment through the perforate drumhead, to the vault of the pharvnx, and to the nose; 2, those amenable to the meatomastoid operation; 3, those only amenable to the radical mastoid operation. The contraindications he gives thus: (a) All simple cases curable by nonsurgical and minor surgical treatment through the external meatus. (b) All cases curable by the proper surgical attention to the epipharynx and the posterior ethmoidal and sphenoidal sinuses. (c) Cholesteatoma of the tympanic cavity. The removal of the cholesteatoma from the tympanic cavity would dislocate the ossicles, and if this is done the radical mastoid operation should be performed as the chief object, the meatomastoid operation, is defeated by the dislocation of the ossicles, namely, the preservation and improvement of the hearing. (d) Epidural abscess with its atrium of infection through the tegmen tympani. It is obvious that in order adequately to drain an epidural abscess in this region the tympanic cavity should be exposed to give access to the atrium of infection, which should be enlarged. (e) Brain abscess with the atrium of infection through the tegmen tympani is a contraindication to the meatomastoid operation for obvious reasons. (f) Infection, suppuration, and necrosis of the labyrinth is a contraindication to the meatomastoid operation, as the affected portions of the labyrinth should be exposed to inspection and if necessary to surgical treatment.

Tuberculosis of the Ear, By W. SOHIER BRYANT.
The Chemical Rays Promoters of Life and Energy:
Their Mode of Action, and Their Therapeutic Uses. Tuberculosis of the Ear, By MARGARET

3. Cuguillère's Serum in the Treatment of Tuberculosis,

- Malnutritis and Society,
 Waginoureterostomy after Nephrectomy for Pyonephrosis Due to a "Sigmate" Constriction of the Ure-By A. Ernest Gallant.
- 1. Tuberculosis of the Ear.—Bryant remarks that tuberculous invasion of the ear is primary or secondary. Primary invasion is direct through the Eustachian tube or through the mastoid lymphatics. Tympanic tuberculosis is a very early sign of a more general infection. It also gives an accurate indication of the course of a concomitant pulmonary tuberculosis. Tuberculous mastoiditis has similar characteristics to tuberculous inflammation of other bones. Prognosis for the ear tuberculosis is good with proper hygiene and early treatment, and early through operative treatment in cases of bone involvement. Pyoctanin dry treatment is the most efficacious for tympanic tuberculosis. The evil effects of a tympanic tuberculosis may cause pulmonary tuberculosis to take a lethal course. The gross anatomy and histology of the tuberculous process in the ear are the same as in other parts of the body made up of mucous membrane, osseous tissue, and lymphatic glands. The two peculiarities which the ear has are, first, that it is a multiple sense organ, and, secondly, that in it the three tissues mentioned are very intimately associated. The bone is lined with a mucoperiosteum and the dura mater forms the inner periosteum. The cold abscess is the rule in ear tuberculosis. The softening and erosion of the mucous surfaces or periosteum and the disintegration of bone and the suppuration progress with little pain and red-Though the ness or without much temperature. presence of tuberculous bacilli can usually be demonstrated in the pus and tissues, sometimes they are most difficult to detect. It is exceptional to find them in the thin secretion of the middle ear.
- 2. The Chemical Rays Promoters of Life and Energy.—Cleaves says that the chemical frequencies of light are the promoters of life and energy. Thermal are never used to the exclusion of chemical frequencies in light therapy. Chemical frequencies are directive or destructive according as they are used. Especially is this true of the irregular disorderly impulse of the x ray as compared with the rhythmic energy of the visible spectrum. The x ray and radium radiations are of great value in many skin conditions, even superficial epitheliomata. in some instances mitigating the symptoms and staying the progress of deep seated malignant processes as well. They are, however, on the other hand, capable, of exciting malignancy and inhibiting physiological function. Bactericidal energy has been located by experiment in the middle third of the ultraviolet region. Skin reaction is established by ultra-violet energy. The best results are secured in deep seated, well organized skin lesions by a complex of the penetrant blue violet and ultraviolet. profound sudation is desired over and above penetrating effects, a source of light affording thermal

with a minimum of chemical energy is indicated. When deep seated effects are desired, sources of light rich in blue, indigo, and violet are indicated. The spectra of the different sources of energy vary in degree, not kind; hence the interlocking of effect secured and result established from the various light sources. When the office equipment affords but one light mechanism preference is yielded the electric arc as providing the maxima of energy required in initiating and establishing necessary physiological processes whether the departure from the normal is characterized by a skin expression or not. More or less profound hyperæmia is established as a result of the use of light, depending upon its length of application and the degree of penetrating power. Upon this depends the rationale of its action. The physiological action of the chemical rays is fundamental to nutrition, and they are an invaluable therapeutical adjunct in the host of chronic conditions characterized by loss of chemical control; they lend themselves to conditions of malnutrition or perversions of nutrition, to both simple and secondary anæmias, controlling hæmorrhagic conditions associated with the latter, as uterine and rectal, for example. They are almost a specific in the annulment of pain, relieving for a time even that from pressure of malignant growths, quieting and steadying nerve action in simple nervousness, storing up energy for the neurasthene, establishing more or less hyperæmia in organic cord conditions, and to that extent holding and preventing extension of the disease, contributing alike to the relief of a simple depression or excitability and to a maniac depressive insanity. They are likewise effectual in absorbing effusions from serous cavities and subcutaneous structures, whether secondary to malignant processes, an inflammation, a leaky heart, or a hydrocephalic effusion associated with rachitis. They also prevent and cut short the progress of infective processes, and cure or improve the many skin expressions of disturbed metabolism. Equally, they may arrest and control respiratory disturbances from a simple catarrhal cold to a bronchial asthma or a pulmonary tuberculosis.

3. Cuguillère's Serum in the Treatment of Tuberculosis.—Caravia gives a favorable account of the results of Cuguillère's serum. He remarks that Cuguillère's serum attacks the disease itself and its direct cause, Koch's bacillus, which it destroys. It helps recovery by promoting the fibrous transformation of the tubercle in whatever organ or organs it exists. It needs no additional drugs to suppress and prevent hæmoptysis, to reduce temperature, to stop diarrhœa and night sweats, to arouse the appetite, to strengthen the heart's action, to increase the weight, to stop cough, expectoration, and pain, to facilitate the resorption of pleural, peritoneal, or articular effusions. Many persons with pulmonary tuberculosis have been cured and are being cured with other drugs and sun and air, and some have been cured without the help of any treatment, but with Cuguillère's serum the recovery is almost mathematically certain, provided the organism has sufficient vitality and recuperative powers and has not fallen into decay. The difference between Professor Detweiller's fourteen per cent. radically cured cases by sanatorium treatment, and Dr. Escover's 53.8 per cent. radically cured by Cuguillère's serum, is eloquent in favor of the serum, especially when we take into consideration the absence in Escover's patients of all the comforts afforded to sanatorium patients. But the unanimous testimony of all physicians and surgeons who have employed the serum on new or far advanced cases of surgical tuberculosis that they had 100 per cent. recoveries, places on Cuguillère's serum the highest therapeutic value, not possessed by any single remedial agent, not even excepting diphtheria antitoxine.

2. Chorea.—Rankin tells us that in true chorea the muscular movements are involuntary, purposeless, and liable to intensification under the influence of mental perturbation or emotional excitement. They cease during sleep. The peculiar and intimate association which exists between chorea, cardiac disease, and rheumatic fever, is well recognized, but its nature has not been ascertained. Chorea rarely occurs under five years of age; about fifty per cent, of all cases are met with between five

and ten years. It attacks girls three times more frequently than boys, and this percentage increases after the second decade. It is most prevalent during cold and damp weather. Certain families are specially predisposed. Recurrences are prone to occur. The proximate cause is probably a microorganism similar to that of rheumatism, the toxines of which are responsible for the nervous phenomena. But the direct excitant of an attack is often some form of emotional disturbance. The onset is usually gradual. Restlessness and clumsiness of movement are followed by erratic contractions of single muscles or groups of muscles. The disorderly character of the muscular contractions is aptly described as a folie musculaire. The parts selected by chorea are those which habitually combine in purposeful and emotional movements. Articulation is more or less impaired, and may be so jerky and explosive as to make the speech unintelligible. Rigidities do not occur, but there is invariably some loss of muscular power. There is a mental element attaching to all cases of chorea, and in extreme cases occurring in adults this intellectual impairment may gravitate into actual mania, and produce that rare and frequently fatal variety of the disease known as chorea insani-There are no marked sensory disturbances in chorea, but aching pains in the back may be complained of. The reflexes are usually normal. Endocarditis and pericarditis are in evidence in the majority of the cases. Almost invariably the action of the heart is abnormally rapid. The disease usually runs a chronic course and lasts, on an average, for from eight to twelve weeks, but remissions and exacerbations may prolong it over six months. The most frequent complications of the disease are those which occur in association with rheumatism. Erythema nodosum and peliasis rheumatica are the most common skin complications. A temporary form of imbecility is not uncommon in several cases. Pulmonary tuberculosis supervenes upon chorea in a fair number of cases. No constant lesions are found in the nervous system which can be regarded as the anatomical basis of the disease. The prognosis in children is favorable as regards recovery from the choreic attack, but there is always the risk of permanent cardiac mischief. In the treatment of the disease, rest, both mental and physical, is of special importance, and is indicated in every case, no matter how mild. The child ought to be put to bed and kept there until all movements cease, so as to minimize the risk of cardiac complications and at the same time expedite the natural tendency to recovery. There is no specific for the disease, but arsenic gives the best results of any drug. Given with butter it is less toxic than when given in solution. In severe cases something must be done to control the muscular movements. Here chloral hydrate acts best, but in desperate cases it may be necessary to give morphine. When the movements are not too violent, warm baths or hot packs may be used with benefit.

6. Diagnosis of Pulmonary Tuberculosis by X Rays.-Leonard states that recent improvements in apparatus and technique have so added to the value of the Röntgen rays in the diagnosis of pulmonary tuberculosis that with instantaneous exposures it is possible to detect bronchial glands and areas of infiltration about the roots of the lungs, where neither percussion or auscultation can reach them, and before the bacteriological test has determined their ætiology and only the symptom complex suggests tuberculous disease. In addition, in the increased detail it secures by the elimination of motion due to the heart's pulsation and involuntary movements during suspended respiration, it furnishes a more precise registration of the affected areas, and shows cavities and areas of softening which lie too deep to be detected by ordinary clinical means.

A Case of Acute Cantharides Poisoning, By J. S. AVERY.

1. Fever in Children.—Cantley divides the cases of anomalous fever in children into two groups. The first and more numerous group includes all those in which no definite cause is found on examination, but data can be discovered for a probable diagnosis, which is more or less verified by the course The second group is composed of those of events. cases in which the most thorough investigation fails to reveal the cause of the fever. In most cases fever is due to the direct effect upon the nervous system and so on the heat regulating centres, of toxines produced in the tissues of the body, or in the food before or after ingestion, by microorganisms or ferments. Feverish new born babies should be examined most carefully for evidences of sepsis, which may originate almost anywhere in the body. It is very improbable that teething is ever a direct cause of fever, but its complications may be so. Among them may be mentioned the bolting of food, local inflammation of the gums, inflammation of the mucous membrane of the mouth, etc. Many an anomalous temperature is due to inflammation of the throat. In acute follicular amygdalitis, or even in diphtheria. there may be no symptoms referable to the throat. The nasopharynx is a common site of infection. Chronically enlarged and pitted tonsils are a potent source of attacks of fever. In the absence of all other evidence one may have to fall back on the alimentary tract as the possible source of the fever. Carbohydrate fever is a name sometimes given to febrile attacks which are apparently the result of an excess of carbohydrate food and cured by strict limitation of the diet. The fever lasts from one to four days, and may reach 104° F. In some cases there are incessant vomiting and constipation. Any of the infectious fevers in their early stages may give rise to fever of uncertain origin. True influenza is often unrecognized and still more often diagnosticated on insufficient grounds. The abdominal type of influenza is often mistaken for appendicitis. The rheumatic poison may cause fever in children in many ways, myocarditis being a cause that is often

overlooked. Pyelitis is a cause of fever that is very difficult of diagnosis. Female infants are especially liable to infection of the urinary tract by the Bacillus coli. In the bladder it gives rise to little or no fever, bacilluria, and sometimes mild cystitis. It is when the bacillus infects the pelvis of the kidney, causing pyelitis, that it gives rise to high fever, the cause of which is overlooked, as it is difficult to obtain the urine of female babies for examination. Nervous, excitable children are prone to irregular pyrexia on slight provocation. Undue exertion, chill, and insufficient clothing are sometimes to blame.

2. Diagnosis of Fever.—Sutherland states that the following postulates may be assumed in any given case of fever: I. The cause of the fever must either be infective or noninfective, but it is almost always the former. 2. If the cause is infectivethat is to say, due to the invasion of a parasite—a parasite of some or other class must be present somewhere, either inside the body or in relation to one of its surfaces, and, unless ultramicroscopic, is in all probability discoverable. 3. Such parasite must either be—(a) bacterial (coccus, bacillus, vibrio, fungus); (b) protozoal (amœba, piroplasma, Leishman-Donovan body, spirillum, trypanosoma, etc.); and (c) vermicular (worm embryo or worm). 4. The infection must either be (a) a local infection of the skin or of some mucous surface of entrance or exit; (b) a general infection of the circulation; (c) an infection of the spleen or a localized infection of the lymph circulation; or (d) an infection from without. 5. If it is a local infection the parasite will excite local reaction wherever it has lodged. which will be likely to reveal itself by local symptoms and physical signs; and probably the parasite will be discoverable in some one or other secretion or pathological discharge. In addition, the blood should show evidence of entry of toxines into it from some one or other source. 6. If it is a general infection of the circulation it must be possible to find the parasite (unless ultramicroscopic) in the blood or to obtain evidence of its presence. 7. If it is an infection of the spleen, or a localized infection in the lymph circulation, the blood should show signs of disorder in some one or other of its hæmopoietic tissues, and it should be possible to find the parasite, or to obtain evidence of its presence, in the spleen, or in some one or other lymphoid or lymphatic structure. 8. A negative finding on all these points would imply that the cause is noninfective.

3. Dental Caries. - Wallace defines dental caries as a chemicoparasitical process, dependent upon the undue lodgment of fermentable carbohydrates and acid forming microorganisms, and consisting of two distinctly marked stages-decalcification or softening of the tissue, and dissolution of the softened residue. The conditions which favor the undue lodgment of carbohydrate food are: (1) those resulting from the nature and constitution of the individual, and (2) those resulting from the nature or constitution of the food. The first group includes peculiarities of the teeth themselves, fissures, pits, developmental defects, and irregularity. Of late years changes have taken place in food stuffs tending to increase the lodgeability of the carbohydrate and acid forming microorganisms. Nowadie almost all the cellulose is cooked, softened, and often extracted from the food, its detergent effect being completely lost. Starch when cooked or boiled becomes pasty, and is easily convertible into sugar, which is rapidly fermentable. Sugar forms a gummy substance, clinging to the teeth, and tending to entangle other substances. It also hampers the action of the saliva, and has an irritating effect upon the mucous membranes. So that, in order to prevent dental caries in children, attention must be paid to the dietary—it should contain cellulose (fresh fruit, bacon, etc.), and should be properly arranged. No meat should be used with sweets,

- By M. BERNHARDT. 2. Localization of Motor Aphasla. - Von Mayendorf sums up the result of his studies with the statement that Broca's place appertains to the motor cortical region. It is not superfluous to emphasize this, because many have asserted that Broca's place conceals a psychic centre ranking above the motor region. It is entirely arbitrary to connect this with the third frontal convolution; it belongs both anatomically and physiologically to the anterior central convolution, and Pierre Marie is right when he ascribes to the third frontal convolution a part in the occurrence of motor aphasia.
- 5. Pancreas Diabetes .- Adler and Milcher allege as the result of their experiments that diseases of the pancreas are not necessarily associated with a steatorrhea, and that in their cases of pancreas diabetes pancreon exerted in no way a favorable influence upon the resorption of fat.
- 7. Serum Diagnosis of Syphilis.-Stern says that the most extreme care must be taken in the interpretation of the results produced by this test, as a positive reaction may be readily mistaken for a negative.
- 9. Dyspnœa of Gastric Origin.—Galli reports a case met with in a man thirty-two years of age, in which dyspnœa was due to air in the stomach, as proved clinically and by the x rays.

 17. Obituary of Dr. Karl Singer, By DEGLE. By DESSAUER
- By FISCHER. 1. Puncture through the Corpus Callosum in Cases of Hydrocephalus, Tumors, and Epilepsy. -Anton and von Bramann do not consider the usual methods of puncturing the cerebral ventricles, or lumbar puncture alone, to have the requisite efficiency in troubles of this nature, and therefore recommend to penetrate the skull near the sagittal suture, pass down between the lobes of the brain, and thrust a blunt cannula through the corpus callosum into the ventricle. They report three cases successfully operated on in this manner, creating openings of communication between the ventricles and the subdural space. They consider this operation to be indicated in cases of hydrocephalus, tumors with hydrocephalus and neuritis from engorgement, hypertrophy of the brain, and the various diseases associated with narrowing of the brain space which
- have been classed as pseudotumors. 4. Experimental Studies Concerning "Tuberculous" Changes in the Skin without Concomitant Action of Tubercle Bacilli.-Zieler shows by his experiments that changes in the skin may be induced which are less characteristic than those induced by cutaneous inoculations of tuberculin, but differ from them only in degree, and must be designated histologically as tuberculous structures by the inoculation of solutions of material arising from the tubercle bacilli containing no corpuscular, or even ultramicroscopic, constituents of the tubercle bacilli and none of their detritus.
- 5. Much's Granular Form of the Tuberculous Virus .- Wirths declares that the granular form of tuberculous virus stainable only by Gram's method is no product of disintegration, but is a virulent form of development and the most resistent known form of Koch's tubercle bacillus, both in the human and in the bovine type
- Treatment of Children with Scarlet Fever. Oppenheimer protests against the use of baths and cold packs, and against the administration of meat, meat broths, and eggs, in cases of scarlet fever as predisposing to renal troubles. He alleges that during the eighteen years he has been in practice he

- has treated over 150 cases of scarlet fever, seen every imaginable kind of complication, lost three cases by death, but has never had a case of inflammation of the kidneys.
- 10. Hydrocele. Mohr speaks favorably of the injection of adrenalin in cases of hydrocele which for any reason cannot be operated on and refill quickly after simple puncture. His experience is that the sack refills more and more slowly after each injection. For operative measures he prefers the operation described by Klapp in 1904 as superior to the older operations of Volkmann and von Bergmann because it can be done under local anæsthesia. and the after treatment may be ambulant.

- Hernia of the Ovary in Infants.-Nicoll observes that in a few cases the development of strangulation gives the first indication of the hernia. In other cases the parents give a history of apparent local discomfort on the part of the infant as leading to the discovery of the swelling. In the large majority of instances, as in the case of inguinal hernia in male infants, the parents simply state that they have observed a "lump" or "swelling" in the groin, which "lump" is said to be constant or intermittent in appearance as the ovary happens to be reducible or not. In a number of the cases the infant presents an ill nourished and puny appearance, and is said to be fractious and troublesome. Treatment should in nearly all cases be operative. In the strangulated case operation is imperative. In the case of the irreducible ovary it is in every sense advisable. The wearing of a protective truss in the infant is impracticable. In the case of the reducible ovary operation would appear to be the rational line of treatment. Truss wearing by the young infant is a troublesome and usually ineffective procedure, and the choice of treatment lies between operation and ignoring the hernia. The latter line has this to be said for it, that in certain cases the hernia disappears without having been strangulated, and is not succeeded by enterocele or epiplocele. On the other hand, the operation has a mortality rate purely nominal. The advantages of operative treatment are as follows:—(a) Prevention of strangulation; (b) prevention of subsequent enterocele; (c) relief from the irksomeness of truss wearing; (d) improvement of the infant's health (in many cases the change from peevish emaciation to plump health is marked); (e) ablation of cysts in the ovary. In

over thirty per cent. of the cases the ovary is found to contain cysts—single or multiple. Such cysts are ablated in various ways—excision followed by suture, evisceration with the sharp spoon, or other method.

6. The Leucocytosis of Whooping Cough.—Crombie says that the cause of the lymphocytosis of whooping cough is somewhat difficult of explanation. If, as is alleged, the specific germ of whooping cough during the catarrhal stage grows upon the mucous membrane of the respiratory tract, then the lymphocytosis may be due to a positive chemotaxis, the result of stimulation of the tracheobronchial lymphatic glands and neighboring lymphoid tissue. The lymphocytes are protective and may act as phagocytes, or may produce an antitoxine capable of dealing with the toxines of the whooping cough germ.

I. Recent Mania: Its Cause and Treatment,

2. Typhoid Carriers, By RICHARD KELLY.
By J. A. PRINGLE.
3. Clinical Reports of the Rotunda Hospital (Continued),
By E. HASTING TWEEDY, JOHN W. BELL, and
ARTHUR FIGURES.

ARTHUR HOLMES. 2. Typhoid Carriers.—Pringle reviews the literature on chronic typhoid carriers, and finds certain points, the observation of which in investigating an outbreak might lead one to suspect a chronic typhoid carrier as the source of infection: The occurrence of the cases at irregular intervals, and in groups, this is particularly noticeable in the cases in institutions, etc. The sporadic nature of the cases occurring in private life. He thinks these carriers will afford a sounder explanation of the existence of enteric infected houses and places than that offered by the supposition that the Bacillus typhosus retained its vitality in dust and crevices, which was the theory hitherto held. Women appear to become carriers more frequently than men in about the proportion of three to one. Of treatment, Pringle says that when one remembers the seat of the infective organism in the body-namely, the gallbladder—and the length of time such cases may continue active agents in the spread of the disease, the immense difficulties encountered in their successful treatment may be more easily understood. In fact, up to the present time, no satisfactory treatment has been found. In the first place there is the practical difficulty of getting such unconscious carriers to remain under surveillance and bacteriological control, and of carrying out continuous and efficient disinfectant measures, though it is clear such precautions are absolutely necessary. Then, as regards the actual treatment, provided isolation and disinfection of excreta can be secured, we have no drug at our disposal which The so called inteswill render the bile sterile. tinal antiseptics have been employed without success. Urotropin, invaluable in dealing with infection of the urinary tract, has not been found successful in causing disappearance of typhoid bacilli from the fæces. Attempts have been made to increase the immunity of the subject against typhoid infection in the hope that by augmenting the powers of resistance a bactericidal effect might be produced on the organism. So far no promising results have been obtained, although this line of treatment offers greater posibilities of ultimate success than any other. In Germany, surgical treatment—namely, cholecystostomy and drainage of the gallbladder—has been adopted by Delher in two cases, though in neither of them were there symptoms pointing to gallbladder disease. In a few months it was found the bacillus disappeared from the fæces, and the patient's serum failed to give Widal's reaction. As a preventive measure Pringle suggests the bacteriological examination of fæces of typhoid patients for a few months after recovery.

 Osseous Plaques of the Piaarachnoid and their Relation

to Pain in Acromegaly, By S. LEOPOLD. 1. Posterior Column Degenerations Following Injury to the Posterior Roots of the Seventh Cervical Nerves.—Mitchell and Barrett report such a case. The patient, a heavy drinker, fell from a hay mow some distance to the floor, and on the following morning was picked up in an unconscious condition. It was observed that his head was turned to the side and bent in a peculiar position. His arms were weak, and it was difficult for him to rise from a chair. He was admitted to a general hospital, and five days later sent to an insane hospital. Here his condition became rapidly worse; below the level of the second rib, excepting for the outer surface of both arms, pin pricks produced no pain reaction, and all voluntary movements were absent in arms and legs; and he died soon. Autopsy showed that the seventh cervical segment presented the appearance of severe injury. The authors conclude that the case presents two interesting anatomical points: First, while the cord at the level of the seventh cervical segment was considerably injured in the anterior, and more especially the lateral regions, the injury to the posterior columns in a peculiar way involved chiefly the entering posterior roots of the seventh cervical nerve, together with a few of the fibres of the sixth, the remainder of the column showing only a small degeneration in the median part. The second and more important feature was the comma tract degeneration, and its relation to the degeneration of the posterior roots. The slight injury to the posterior columns as a whole, and the marked involvement of the entering nerve roots had an important bearing on the origin of the fibres of the comma tract, and their exogenous origin. Three opinions are maintained in the literature as to the origin of the comma tract-first, that they are of endogenous origin, i. e., fibre processes of cells of the posterior horn; second, that they are the downward continuation of fibres of the posterior roots; third, that they are made of both endogenous and exogenous fibres. The conditions present in this case seem to lend evidence to their exogenous origin, because of, first, the marked degeneration of the posterior nerve roots as they enter the cord, and, second, a lack of any significant direct injury to the posterior columns or the nerve cells of the posterior horns, none of which show the changes which are characteristic of an injury to the fibre process of a cell.

2. Osseous Plaques of the Piaarachnoid and their Relation to Pain in Acromegaly.—Leopold summarizes his article: Osseous plaques are frequently present in the piaarachnoid. They are found in many diseases, such as uræmia, tuberculosis, retogressive conditions, etc. Arteriosclerosis seems to be the underlying factor in their causation. The presence of these plaques upon the spinal pia in acromegaly does not explain the production of pain in that disease. There is no definite pathology of the spinal cord in acromegaly.

 Syphilis in Pregnancy and Early Infancy, By A. B. Morse.

- 3. The Treatment of Acute General Septic Peritonitis.-Ross thinks the treatment of this grave condition should be first surgical, and at a very early period, and then medical, including the old Clark treatment, with larges doses of opium if necessary. Operations should be performed early, rapidly, and the chances of subsequent infection should be removed by the complete closure of the abdominal cavity. Rigidity of the abdominal muscles is the indication that the disease is present. Neither drainage nor posture have served the author well. An ample incision having been made, the author irrigates thoroughly with warm saline solution the five pools in which pus accumulates, one under the liver, one under the spleen, one in each loin, and one in the pelvis. The source of infection should be found, if possible, and closed by approximating sutures, or shut off by gauze packing. The intestines should be handled as little as possible, and no attempt made to wipe away lymph deposits. The author's formula would be operate early, incise amply, repair carefully, wash thoroughly, manipulate gently, perform rapidly, close completely, and narcotize deeply.
- 5. Heart Disease and Pregnancy.—Cameron thinks the physician should forecast the probable effects of pregnancy and labor upon his patients who are suffering with heart trouble, and that the obstetrician should know the extent to which endo-

carditis and chronic valvular disease may modify or derange the course of pregnancy, labor, and the puerperium in those whom he may attend. must remember that different forms of heart disease affect pregnant women in different ways, and that it is important to make an exact diagnosis before beginning treatment. The majority of patients with heart lesions may bear a living child with safety, but each recurring pregnancy aggravates the heart lesion. A cardiac lesion may exist before pregnancy, the latter condition then being a complication, or the heart lesion may be latent and be developed by pregnancy, or it may begin during pregnancy or the puerperium, being then a complication of pregnancy. With regard to the degree of danger heart lesions during pregnancy may be considered. in the following order: mitral stenosis, aortic insufficiency, mitral insufficiency either alone or complicated with stenosis or some aortic lesion.

Hourglass Contraction of the Uterus during Labor.-Sothoron states that the commonly suggested causes of this condition are irritation within the uterus, abuse of ergot, abnormal adherence of the placenta, and prolonged use of chloroform or ether. The condition may be recognized by the abnormally high position of the fundus, by elastic feel of the cord without attending pains, while on palpation the uterus is found irregularly contracted. The treatment depends on two conditions (1), a partly adherent placenta in a cavity with poorly contracted walls, resulting in hæmorrhage, (2) a retained nonadherent placenta in a cavity with well contracted walls, and little or no hæmorrhage. The following conclusions are offered: (1) Avoid meddlesome midwifery, such as early rupture of the membranes before dilatation is complete. (2) Avoid ergot and similar drugs until the third stage of labor is concluded. (3) Avoid interference with normal uterine action by prolonged use of chloroform or ether. (4) Avoid the danger of stimulating spasmodic uterine contraction as well as danger of rupture of the cord by an attempt to deliver an adherent placenta by traction on the cord. The remedy suggested for the relief of the contraction is the gradual introduction of the hand, the placenta being removed with its withdrawal.

Proceedings of Societies.

SIXTH INTERNATIONAL CONGRESS ON TUBERCULOSIS.

Held in Washington, D. C., September 28, 29, and 30, and October 1, 2, and 3, 1908.

Dr. William H. Welch, of Baltimore, in the Chair. Section I.—Pathology and Bacteriology.

In opening the meeting of the section, the chairman said that the work of the section included all work on which the rational and intelligent attempts to control the disease must be based. The methods adopted for the prevention of the spread of tuberculosis should always be based upon an exact:

knowledge of the cause of the disease and its method of diffusion, if they were to be productive of the most good. He then announced the list of

honorary presidents of the section.

The Viability of the Tubercle Bacillus.-Dr. MILTON J. ROSENAU, of Washington, said that the tubercle bacillus was uniformly considered to be unusually resistant to methods designed to destroy it. It was formerly thought to be a spore bearing organism, but he was of the opinion that it did not contain spores. The fatty and waxy constituents which surrounded the bacillus after the fashion of a capsule, together with the acid fast properties of the organism, were thought to be further indications of its resisting powers. Unfortunately, there was no satisfactory criterion of the death of the Bacillus tuberculosis except secondary animal inoculations. The reactions produced by tuberculin were just the same when the bacillus was dead. He said that his own work indicated that exposure to a temperature of 60° C. (140° F.) for twenty minutes would kill the bacillus. The organisms usually died in three months; in dried sputum they would live sometimes for many months. He considered that the Bacillus tuberculosis approached the other nonspore bearing bacilli very closely in all its cultural characteristics.

The Action of Diffused Light upon the Bacillus Tuberculosis.—Professor John Weinzer, of Seattle, said that the Bacillus tuberculosis was killed in from two to ten minutes by exposure to direct sunlight. When exposed to diffused light, it was always killed within a week and in some cases within twenty-four hours. When the bacilli were dried and exposed to diffused light, they lived longer than moist cultures. It appeared certain that diffused light materially shortened the life of the

bacillus.

A Chamber in which Dried Tubercle Bacilli may be Handled Without Danger.—Dr. ARTHUR P. HITCHENS, of Glenolden, Pa., described a glass chamber in which tuberculins and the dried products of the tubercle bacillus might be handled without danger to the operator. The essential feature of the chamber was the method by which rubber gloves with long arms were fastened to the front glass face of the chamber. A partial vacuum was maintained within the chamber by the use of a pump. After the preparation was made, it was tightly sealed in a bottle and formalin was generated in the chamber, which was left sealed over night.

Section II.—Clinical Study and Therapy of Tuberculosis; Sanatoria, Hospitals, and Dispensaries.

Dr. VINCENT Y. BOWDITCH, of Boston, in the Chair.

Typhobacillosis.—Professor L. Landouzy, of Paris, spoke of a type of acute tuberculosis which was originally described by him in 1883. He considered it both pathologically and clinically one of the most distinct and clearly defined manifestations of acute septichemia due to the bacillus. It presented itself in the form of a typhoid state with continuous fever and enlargement of the splcen and without signs of visceral localization. The fever

was more irregular than that of typhoid fever, there was a lack of correspondence between the pulse rate and the temperature, the pulse was more rapid than in typhoid fever, and there were no localizing symptoms in the viscera. He said that there were no rose spots and that every case of typhoid fever in which rose spots were lacking should be suspected. If the patient died, nothing would be found but the ordinary congestive and degenerative lesions seen in all severe septichæmias. The disease often terminated favorably in three or four weeks. But the convalescence was imperfect, and at the end of a few weeks or many months localized signs of tuberculosis appeared in the lungs, the pleura, or the mesentery. Of course the serum reaction with Bacillus typhosus was negative; inoculation of a guinea pig with the patient's blood produced tuberculosis in the animal. The serum reaction of d'Arloing and Courmont, and the ophthalmic reaction were considered of value in making a diagnosis. He referred to experiments on rabbits and guinea pigs, which indicated that such a condition as typhobacillosis existed.

The Duration of the Actively Infective Stage of Tuberculosis .- Dr. ROBERT N. WILLSON and Dr. RANDLE C. ROSENBERGER, of Philadelphia, reported the results of the study of one hundred cases of tuberculosis in which the urine, the sputum, the fæces, the semen, the blood, the spinal fluid, and pleural and peritoneal exudates were examined for tubercle bacilli. In the majority of cases the organisms were found in at least one of the main excretions, and sometimes in all three of them. In five out of eight cases the semen contained tubercle bacilli at the time of autopsy. The organisms were found in the fæces in every case in which they were found either in the sputum or in the urine, and in many cases of acute miliary tuberculosis and of glandular tuberculosis. The duration of the viability of the organisms varied greatly when they were allowed to dry in full sunlight. They found that there was no limit to the duration of infectiveness even of the dried excretions; the bacilli lived in water for more than a year. In animal experiments they found tubercle bacilli in the urine and fæces within the first week, before either cough or sputum appeared. The presence of living tubercle bacilli in the urine and in the fæces was of importance in relation to the infectiveness of sewage and of drinking water.

SECTION III.—SURGERY AND ORTHOPÆDICS.

Dr. CHARLES H. MAYO, of Rochester, Minn., in the Chair.

Tuberculosis of the Larynx: the Type which is Capable of Recovery and the Principles of Treatment.—Dr. W. E. Casselberry, of Chicago, said that certain persons acquired a natural resistance sufficient to arrest laryngeal tuberculosis, and that many persons offered a considerable resistance which was only just short of the degree required for arrest. Tuberculous hyperplasia in the larynx might undergo resolution, and unmistakable tuberculous ulcers did occasionally heal.

A Brief Note upon the Value of the Ophthalmic Tuberculin Test in the Question of the Surgical Treatment of Orbital Disease. — Dr.

CHARLES A. OLIVER, of Philadelphia, said that ophthalmic tuberculin tests, judiciously used, were of value in the diagnosis of tuberculosis of the corresponding eye and its annexa, particularly in primary infections. They should form a part of the routine study of every doubtful case of orbital dis-Positive reease before an operation was done. sults should be followed by tuberculin treatment. The conclusions of Dr. Oliver were based upon the observation of three cases.

Tuberculosis of the Cornea.—Dr. OSCAR DODD, of Chicago, said that tuberculosis of the cornea was nearly always secondary. It was usually preceded by a swelling at the corneal margin resembling phlyctenular conjunctivitis. Tuberculin injections for diagnostic purposes caused a general and a local reaction, which was manifested by a marked inflammation of the eye, more infiltration into the cornea, and the formation of new foci. The use of T. R. in small doses was followed by the disappearance of the spots without opacity. Too large a dose was followed by an increase of infiltration, which persisted for several days.

Tuberculosis of the Ear .- Dr. CLARENCE JOHN BLAKE, of Boston, described a form of tuberculosis of the middle ear and the labyrinth which was characterized by considerable and rapid destruction of all tissues, without preliminary subjective symptoms. The infection probably gained the tympanum through the tympanopharyngeal tube. The diagnosis was to be made by careful aural examina-

Tuberculosis of the Nose, Mouth, and Pharynx. -Dr. H. P. Mosher, of Boston, said that primary tuberculosis of the nose was rare; when present it was characterized by a superficial ulceration over the anterior part of the cartilaginous sæptum. Secondary tuberculosis of the nose was characterized by the production of tuberculous tumors. It was usually slow and progressive, but did not extend to the pharynx. It was to be diagnosticated from Tuberculous lesions were found in all parts of the mouth; ulceration was the common lesion, although a tuberculous tumor or a tuberculous abscess might occur. Tuberculous lesions of the mouth were often started by an injury. berculosis of the pharynx was a common secondary infection from a pulmonary lesion. Extensive pharyngeal lesions interfered with swallowing and ended fatally. Tuberculosis of the tonsil was secondary to pulmonary tuberculosis; but in five per cent. of the cases it was primary. The pharyngeal tonsil was infected by the air current, the faucial tonsil by the food. He was of the opinion that tuberculosis of the tonsil rarely caused pulmonary or general tuberculosis. The great importance of tonsillar tuberculosis was the frequency of cervical lymph node tuberculosis as a secondary lesion. Cervical tuberculosis was limited to the lymph nodes of the neck and seldom gave rise to tuberculosis of the apex of the pleura or lungs. Tuberculous tonsils should be removed by thorough dissection. Tuberculosis of the nose, the mouth, and the pharynx should be treated with thorough curetting and lactic acid. In small primary lesions tuberculin seemed to have a special field.

(To be continued.)

New Inventions.

A CLAMP FOR DIRECT TRANSFUSION OF BLOOD.

By ISAAC LEVIN, M. D.,

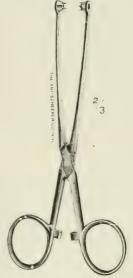

New York.

Dr. Crile, of Cleveland, has recently taken up anew the question of the treatment of acute anæmia, surgical shock, and similar conditions with direct transfusion of blood. There is no doubt that with the present high development of surgical technique and asepsis it is possible to perform the operation with no danger to the donor and with comparatively little danger to the recipient, the more so as the patients on whom the operation is usually attempted are in a desperate condition.

In order to be successful, the operation demands not only a perfect asepsis, but also as much expedition as is possible in the work. Dr. Crile (Annals of Surgery, September, 1907) abandoned the arterial suture and devised for the anastomosis a ring which presents practically a short bloodvessel cannula with a handle. The clamp which I present here I think requires a less complicated technique and less time for the performance of the operation

than Crile's instrument does.

I shall first give Dr. Crile's own description of his technique: "A cannula whose bore is larger than the actual tissue thickness of either vein or artery is selected. The vein may then be pushed through this tube, after which the freed end is turned back like a cuff and snugly tied in the second groove. During this time the handle of the cannula is stead-

ied and manipulated by means of a forceps. artery is then drawn over the vein and is snugly tied with a smal! linen ligature in the first groove.

The clamp devised by me presents an artery clamp without the grooves. At the tip of each blade there is attached a small cannula with a smooth bore. At the inner edge of each cannula there are attached four small pin points, and on the outer surface of the cannula there are cut out four grooves. When the clamp is closed, the pins of one cannula lie in the grooves of the other. The cannulas have a pyramidal form because the pins are bent outward. At the beginning of the operation both halves of the clamp are separated. The vein is pushed through one cannula and its wall is hooked on the pins. The same is done with the artery and the other half of the clamp. Then both halves of the clamp are united and clamped. I believe that when we deal with small bloodvessels it is much easier to hook the walls on the pins than to turn them back like a cuff. When the clamp is closed, both bloodvessels are connected with the serous surfaces.

I have performed several operations on dogs, uniting the femoral vein of one dog to the femoral artery of another. The transfusion was kept up for over half an hour, until the donor was practically exsanguinated. There was no clotting, leakage, or any other defect in the clamp.

Book Antices.

We publish full lists of books received, but we acknowledge no obligation to review them all. Nevertheless, so far as space permits, we review those in which we think our readers are likely to be interested.]

Subcutaneous Hydrocarbon Protheses. By F. Strange Kolle, M. D., Author of The Recent Röntgen Discovery, etc. New York: The Grafton Press, 1908. Pp. 153.

In the preparation of this handsome brochure the author has been actuated by a desire to place before the profession a treatise at once practical and concise, dealing with the subcutaneous employment of hydrocarbons for the correction of defects about the face, neck, and shoulders. The importance of this development of cosmetic surgery is, in his opinion, undeniable, and it has, he maintains, superseded certain extensive operative procedures, notably in rhinoplasty, "giving results that no surgeon could hope to attain under the former laws of surgery." In support of this contention he has cited the experience of no fewer than one hundred and twenty contributors to the literature of the subject; and it must be admitted that he has presented an exceedingly strong case.

After referring to Dr. J. Leonard Corning's pioneer undertakings with solidifying oils in neurological surgery, Kolle enters promptly upon a detailed discussion of the application of the principle to the correction of defects about the face, neck, and shoulders. In this connection the indications, the advantages, the untoward results, and the absorption and disintegration of the paraffin are thoroughly gone into. On page 34 the author adverts to the difficulty of procuring paraffin with a proper melting point, and makes note of the fact that, while ten operators of experience recommend a melting point ranging from 104° to 115° F., three others advocate one considerably higher, viz., from 133° F. to 148° F. Very explicit directions as to the technique of the injections, supplemented by numerous illustrations of instruments and cases, lend a real

value to the book, and an elaborate index and a list of authorities cited in the text help one to ready reference.

Adenomyoma of the Uterus. By Thomas Stephen Cullen, Associate Professor of Gynæcology in the Johns Hopkins University. Illustrated by Herman Becker and August Horn. Philadelphia and London: W. B. Saunders Company, 1908. Pp. xiii-270.

This is another noteworthy addition to the series of gynæcological contributions emanating from Johns Hopkins University, quite in keeping with the standard work which has preceded it.

The author established for himself the reputation of a conscientious and thorough worker a few years ago by his monograph on cancer of the uterus, and now he has extended his reputation by the present work.

The subject of adenomyoma of the uterus, and nothing else, is included in these pages. Its origin from the glands of the uterine mucosa is demonstrated by the analysis of a large series of cases in which the tumors had developed into all portions of the uterus and surrounding structures. Its association with malignant growths is also shown.

To say that the book is illustrated by Becker and Horn means that the same beautiful and accurate work with which students of gynæcology have been familiar these ten years or more forms an important feature of it.

The clarity of the text is admirable. It is a book in which the gynæcological surgeon will be especially interested, and it is unqualifiedly commended.

Beiträge zur allgemeinen Kolloidchemie. Von Dr. B. SZIL-ARD, Paris, Dresden: Theodor Steinkopff, 1908. Pp. 41. (Price, M. 1.50.)

The chemistry of the colloidal bodies is assuming increasing importance in medical teaching, and the pamphlet by Dr. Szilard dealing with the behavior of the organic colloidal substances is calculated to be of special value to students of physiological chemistry, the relationship of the inorganic to the organic being very clearly indicated in the text and by tables, though the author does not attempt to do more than express in a general way the theories which he entertains regarding the behavior of the colloidal bodies as developed by studies in ionism.

Transactions of the American Association of Genitourinary Surgeons. Twenty-seventh Annual Meeting, May, 1907, at Washington, D. C. New York: The Grafton Press, 1908.

The thirty-three papers and theses contained in this volume represent a vast amount of valuable material and a great variety of subjects. Many of the papers have already been published in the current medical journals and are familiar to the profession. It is difficult to select articles for comment among such a set of excellent contributions as this volume contains, but we might mention especially those of Dr. Edward Martin, on epididymovasostomy as a cure for sterility; of Dr. H. H. Young, on the diagnosis of calculi incarcerated at the lower end of the ureter; of Dr. L. G. Cole, on the radiographic diagnosis of renal stones; of Dr. F. S. Watson, on renal drainage; and of Dr. Howard Kelly, on mensuration in urinary diseases. A very interesting and well illustrated article by Dr.

Tilden Brown, on the development of his cystoscope since 1900, closes the volume. The book is well printed and the illustrations are unusually clear and well got up.

Zur Differentialdiagnose der Poliomyelitis anterior acuta (Myatonia congenita [Oppenheim] und Polyneuritis), Inaugural-Dissertation zur Erlangung der Doktorwürde an der Friedrich-Wilhelms-Universität zu Berlin. Von J. VICTOR HABERMANN, A. B., M. D., ehemals vol. Assistent an dem Eppendorfer Krankenhaus zu Hamburg und an der königlichen Charité zu Berlin. Berlin: S. Karger, 1908. Pp. 48.

In this short thesis the author reviews some of the atypical cases of poliomyelitis and of myatonia congenita, and endeavors to point out the essential resemblances and differences. He passes in review the hypotonias due to myxœdema, mongolism, and rhachitis, the paralyses and atrophies due to hæmatomyelia, infantile aplasias of the spinal cord, muscular dystrophy, and polyneuritis. Special interest with reference to polyneuritis attaches itself to the polyneuritic type of poliomyelitis as described by Wickman in the recent Swedish epidemic, and also noted by Harbitz and Scheel in their studies. These latter observers feel that the possibility of a complicating neuritis in poliomyelitis is an open question, and Habermann is inclined to hold the same opinion.

The difficulties of diagnosis are becoming more and more evident with increasing experience, and neurologists and general practitioners alike will welcome this excellent though short summary.

Army Intelligence:

Official list of changes in the stations and duties of officers in the medical corps of the United States Army for the week ending September 26, 1908:

ALLEN, J. H., Captain. Granted leave of absence for one

month in the United States.

Brewer, I. W., Medical Reserve Corps. Left Fort Warren, Mass., on leave of absence for thirteen days.

Brown, H. L., Captain. Granted leave of absence for

five days. CAMPBELL, G. F., Medical Reserve Corps.

San Francisco, Cal., from Philippine Service, ordered to Alcatraz Island, Cal., for duty at the Pacific Branch, United States Military Prison.

CLARKE, J. T., Major. Granted leave of absence for one month in the United States.

W. R., Captain. Left Fort Mason, Cal., for duty with Company B, H. C., en route to camp at Atascadero, Cal.

Ferguson, J. B., Medical Reserve Corps. Recently appointed from contract surgeon, United States Army, ordered to active duty.

HUNTINGTON, P. W., Captain. Granted an extension of

one month to present leave of absence.

JACKSON, T. W., Medical Reserve Corps. Arrived at San Francisco, Cal., on leave of absence for one month

francisco, Cai., on Rayo or abstraction from Philippines Division.

FER, F. R., Major. Ordered from San Francisco, Cal., to Presidio of Monterey, Cal., and thence to camp at Atascadero.

PURNELL, H. S., Captain. Granted leave of absence for two months, to take effect about November 1st.

Scorr, G. H., Captain. Granted an extension to present from duty at Fort Logan, Colo., at the expiration of present leave of absence to include October 31st; relieved from duty at Fort Logan, Colo., at the expiration of present leave of absence, and ordered to proceed on transport sailing November 5, 1908, to Manila, P. I.,

for Philippine service.

Stedman, C. J., Captain. Ordered to return from American Lake, Wash. to Fort Stevens, Ore.

Van Poole, G. M., Captain. Granted four months' leave of absence, when services can be spared

VEDDER, E. D., Captain. Arrived at Fort Walla Walla, Wash., from four months' leave of absence. Weed, F. W., Captain. Left Plattsburg Barracks, N. Y.,

on leave of absence for one month.

The following named medical officers have been relieved from duty at present stations and ordered to proceed to Washington, D. C., and report October 1st, for a course Washington, D. C., and report October 1st, for a course of instruction at the Army Medical School: L. C. Garcia, S. F. O'Day, A. D. Tuttle, E. C. Hill, C. A. Treuholtz, R. W. Kerr, C. G. Snow, W. S. Shields, C. E. Doerr, A. D. Parce, D. W. Harmon, L. R. Dunbar, J. C. Magee, A. Mueller, F. S. Wright, N. L. McDiarmid, G. D. Heath, Jr., J. B. H. Waring, A. D. Davis, C. E. Fronk, D. P. Card, W. H. Smith, W. R. Dear, R. C. Bayly, R. H. Goldthwaite, J. A. Wilson, T. J. Leary, D. Miner, G. H. McLellan, M. C. Stayer.

Navy Intelligence:

Official list of changes in the stations and duties of officers of the medical corps of the United States Navy for the week ending September 26, 1908:

GARDNER, J. E., Medical Inspector. Ordered to additional duty at the Naval Recruiting Station, Boston, Mass., and to duty in attendance upon officers of the Navy and Marine Corps residing in Boston not otherwise provided with medical aid.

FISKE, C. N., Passed Assistant Surgeon. Detached from the Naval Recruiting Station, Boston, Mass., and or-dered to the Naval Recruiting Station, Minneapolis,

HATHAWAY, G. S., Passed Assistant Surgeon. Commissioned a passed assistant surgeon from August 1, 1908. JOHNSON, L. W., Assistant Surgeon. Appointed an assistant surgeon from September 17, 1908.

Lando, M. E., Assistant Surgeon. Ordered to the Naval Recruiting Station, Buffalo, N. Y.

McDonell, W. N., Passed Assistant Surgeon. Detached from the Naval Recruiting Station, Minneapolis, Minn.; ordered to Washington, D. C., to report to the Surgeon General of the Navy for temporary duty, and thence to the Naval Academy.

Shippen, L. P., Assistant Surgeon. Appointed an assist-

ant surgeon from September 17, 1908.

The following assistant and acting assistant surgeons have been detached from the place opposite their nar-and ordered to the Naval Medical School, Washington, D. C., for a course of instruction:

CHAMBERS, W., Assistant Surgeon, from the Naval Recruiting Station, Buffalo, N. Y.

CLARK, G. F., Acting Assistant Surgeon, from the Lan-

caster. Crow, G. B., Assistant Surgeon, from the Navy Yard,

Marfol, Va. HARLAN, T., Acting Assistant Surgeon, appointed an act-

ing a 1-tant surgeon from September 17, 1908

KERR, W. M., Acting Assistant Surgeon, from the Naval Hospital, Norfolk,

MANN, W. L., Acting Assistant Surgeon, from the Naval Hospital, Newport, R. I. SMITH, C. W., Assistant Surgeon, from the Naval Hos-pital, Portsmouth, N. H.

SUTTON, D. G., Assistant Surgeon, from the Franklin. Toulon, A. J., Assistant Surgeon, from the Naval Hos-

pital, Boston, Mass.

ZIEGLER, J. G., Acting Assistant Surgeon, from the Naval Hospital, Pensacola, Fla.

Births, Marriages, and Deaths.

Born.

TRUBY.—In San Francisco, California, on Sunday, September 13th, to Dr. Albert E. Truby, Medical Corps of the United States Army, and Mrs. Truby, a daughter.

Married.

AUCHINCLOSS--NEWLANDS .-- In Franconia, New Hampshire, on Tuesday, September 29th, Dr. Hugh Auchincloss, of New York, and Miss Frances Newlands.

CAMELON—HARTWELL.—In Detroit, Michigan, on Tuesday, September 15th, Dr. Thomas P. Camelon, and Miss

Edith Leroy Hartwell.

HILL—ATWATER.—In Poughkeepsie, New York, on Sat-urday, September 19th, Dr. Eben Clayton Hill, United States Army, and Miss Lucy Lovell Atwater.

States Army, and Miss Lucy Lovell Atwater.
HUNTINGTON—STANLEY.—In Washington, D. C., on
Wednesday, September 23d, Dr. Philip W. Huntington,
United States Army, and Miss Elizabeth Stanley, sister
of Dr. A. C. Stanley, United States Navy.
Morgan—Andrews.—In Washington, D. C., on Friday,
September 18th, Dr Francis P. Morgan and Mrs. Elizabeth Addition

beth Andrews.

SINGER—VAN ARSDALE.—In Pueblo, Colorado, on Tuesday, September 15th, Dr. W. F. Singer, and Miss Bessie Van Arsdale.

THAYER-HILL.-In Belgrade, Maine, on Wednesday, September 16th, Dr. Nathan Pulsifer Thayer, of Brooklyn, New York, and Miss Gertrude Mary Hill, of Brookline,

VINCENT-KNOX.—In Ludington, Michigan, on Thursday, September 17th, Dr. Frank W. Vincent, and Miss Frances G. Knox.

Bell.—In Haverhill, New Hampshire, on Wednesday, September 16th, Dr. John Bell, of Chelsea, Massachusetts,

aged seventy years.

Bradin.—In Newark, New Jersey, on Thursday, September 24th, Dr. Edward De Lancey Bradin, aged fiftyfour years.

Brown.-In Springfield, Massachusetts, on Saturday, September 19th, Dr. John P. Brown, aged seventy-five

Edson.-In Cortland, New York, on Saturday, September 19th, Dr. H. S. Edson, aged seventy-three years.

Epley.—In New Richmond, Wisconsin, on Wednesday,

September 23d, Dr. F. W. Epley. Grant.—In Richmond, Indiana, on Monday, September

21st, Dr. George H. Grant. Guerin.—In Columhus. Ohio. on Tuesday, September

GUERRN.—In Columnus. Office on Tuesday, September 15th, Dr. Zophar F. Guerin, aged eighty-eight years. Harrison.—In Richmond, Virginia, on Sunday, September 20th, Dr. Jacob Prosser Harrison, aged seventy-four

HEGEMAN.-In New York, on Wednesday, September

Hegeman.—In New York, on Wednesday, September 23d, Dr., John A. Hegeman, aged fifty-six years.
HUNT.—In Leipsic, Indiana, on Tuesday, September 22d, Dr. F. P. Hunt, aged fifty-eight years.
JUST.—In Syracuse, New York, on Sunday, September 13th, Dr. John A. Just, aged fifty-four years.
LATIMER.—In West Palm Beach, Florida, on Saturday, September 26th, Dr. Charles E. Latimer, aged seventy-eight west. eight years.

eight years.

McBean.—In Detroit, Michigan, on Wednesday, September 16th, Dr. James C. McBean, aged forty years.

Pardee.—In Ashtabula, Ohio, on Friday, September 18th, Dr. W. C. Pardee, of Cleveland, aged sixty-five years.

WILDER.—In Newark, New Jersey, on Friday, September 18th, Dr. Alexander Wilder, aged eighty-five years.

THE MECHANICOBIOLOGICAL STANDPOINT IN MEDICAL PROBLEMS.

> By Jonathan Wright, M. D., New York.

I .- The Physical Processes in Immunity and Infection.

In returning again to urge the advantage to be secured in medicine from a point of view in biology that comprehends in its sweep of vision the field of physical phenomena, in which of late so much advance has been made both in theory and demonstration, I only join in a sentiment which is every day becoming more widespread among progressive men. This growing appreciation of the unity of physical and biological science seems to render any further peroration on my part superfluous, and I must seek a more valid reason for resuming the subject of physical laws in vital processes. It is in fact a two fold reason. First-I desire to summarize in the briefest manner possible what I have already presented at length, chiefly in this Journal. Secondly—I wish to refer to such additional facts as have been noted in fields bordering on the domain of medicine proper, especially such as are suggestive and helpful in the exploration of that domain itself.

It has been shown that dust or inanimate matter passes through the tonsillar epithelium.1 It has been shown that oil globules, at once saponified when applied, also readily pass." It has been shown that bacteria of the same size as the dust and oil globules do not usually pass, though constantly in contact with the epithelium of the tonsillar crypts. It has been noted that dust (carmin) particles when applied pass through the layer of bacteria on the surface and on into the tonsillar structure without carrying in any of the bacteria.3 Yet we know that under certain conditions bacteria, especially the pathogenic bacteria, do pass through the epithelium both of the tonsils and of the intestines. I have attempted to show from collateral evidence that this action probably arises from the difference between the potentials of surface tension of the epithelial cell on the one hand, and of that of the bacterium and the dust particle on the other. Since the one

is a living colloid state of matter, and the other is so called inert matter, we could hardly expect any other experimental result than has been obtained. How has this distinction arisen in the animal organism? I have attempted to show that the one kind of matter being often harmful and the other kind of matter usually harmless evolution, by natural selection or otherwise, has stepped in, and in the phenomena exhibited by the tonsil we find evidences of its influence.3

I have referred to the experiments of Loeb as furnishing a possible physical explanation of just how the difference of potential comes about, where-by at one time the *Streptococcus* or the *Staphylo*coccus pyogenes, for instance, is excluded and at other times (cold taking, infection, etc.), it is allowed to enter. For, knowing as we do that these germs and perhaps others are more or less constantly found on the surface of the tonsil in health, and beneath the surface in disease, we must have some sort of an explanation of how this surface tension may be made to vary. Loeb, by passing a current of electricity parallel to but not touching a nerve trunk induced a current in the nerve, electrolytic as it appeared, since he showed that certain alkaline salts, by ionic convection, arose at the terminal filaments of the nerve. With his further demonstration that these salts are associated with the stimulus whereby the muscle contracts we are not directly concerned. If we are allowed to conclude that the ions of these salts arise at the filaments terminating in the peripheral cells, a suggestion of which we may find in the saponification of fats on the surface of the intestine, and on the tonsil in my experiments, we can readily understand how the surface tension might be altered by a molecular disturbance of the sympathetic nerve system which we have long recognized as lying at the basis of cold taking and some other infections. This falls in so well with what we know from clinical experience, pathological observation and experiment, that we may look upon it as highly probable the thing comes about in the way I have outlined here and more fully developed elsewhere.

In watching under the microscope for evidence that the carmin granules enter the epithelial cells in their path to the deeper lymph channels, I was unable to see that they did so. In fact phagocytosis during quiescent conditions of the tonsil does not seem to take place in the superficial regions of

Condale: Archa, fur Laryngologic, vii, p. 90; Hendelsolin Discon, viii, p. 456 Wight New York Meshcul Journal, January 6, 1906. Wright: Pudem, January 20, 1906.

⁴Wright: Ibidem, March 23, 1907. Weight Ibidem, August 8, 1908. University of California Publication. December 3, 1905.

the tonsil which furnished the fields of my observations. It would seem that the forces which take the carmin granules beneath the surface are those with which we are familiar under the name of capillary attraction, but as I hope to show elsewhere the action is more complex.

"The assimilation of a poisonous protein which leads to the destruction of the cell with which it becomes united is believed to be on all fours with the assimilation of a nutritive protein which leads to the growth of the cell, or its repair after it has undergone the waste which accompanies activity."

Some discriminating power must preside at the gateways of absorption or protoplasm would cease to exist. Indeed it does cease to exist whenever this power is held in abeyance. In considering this question of surface absorption we must consider the phylogeny of the function. We must think of that simple organization of protoplasm, as in the protozoa where there is no intestinal canal, where every thing which is allowed to pass, passes in unmodified from the environment. There is no saliva nor gastric juice nor pancreatic fluid here to modify things, but selection must be made, from the unaltered material, of that which is nourishing or at least harmless and rejection of that which is harmful, not by the aid of sight or smell; they are the higher specialized functions for food getting and food selection; not by instinct-all these are the products of evolution-, but by the unaided simple reactions of the manifestations of energy, the forces of attraction and repulsion. Bacteria, the internal parasites, even the tapeworm depend directly upon this undifferentiated application of energy.

The recent observations of Albrecht⁸ lend color to the view of the subject which I have urged here and elsewhere. He stained tadpoles tails intra vitam with neutral red and observed that the subepithelial spaces of the connective tissue communicate freely with the surface through interstices of the epithelium. On examination with high penetrating power objectives these interepithelial channels were seen to be bridged across by rafters. These channels, thus partly interrupted, communicate directly with the connective tissue spaces. It was perceived that the cells are not bound to one another by interlacing fibres across these channels, but these rafters are in reality thickenings of the cellular walls and lie in apposition except where they are separated by the interposition of drops of a fluid which is evidently a watery emulsion of a lipoid substance. This varies in physical constitution with the layer of cells in apposition to which it lies—and the surface tension of the drop varies with the chemical constitution (alkalinity?) of the lipoid. This lipoid substance, he concludes from the osmotic currents betrayed by his color granules, is derived through the cell body from the nucleus by molecular interchanges. This process may include a combination of the chemical, the electrical, and the nerve phenomena which play the chief part in the conflict between immunity and infection. The union of the fat compounds with the alkaline salts

in making an emulsion, is, in this connection a suggestive reaction, since the state of saponification is physically largely one of different degrees of surface tension between the fat globules and the alkaline water. It is the lipoid substance lecithin, in cells, as we know from the investigations by Kyes and Sachs' on the cobra poison, whereby a complement is furnished or a link is forged or a stereoscopic valence is formed for the disastrous reception of the poison in the architecture of the cell. Albrecht observed that the part of the fluid which is in close exchange with the basal nuclei of the epithelial cells, exhibits a greater richness of the lipoid substance. This is revealed by the deeper hue given to the fluid at this point, an appearance familiar to all microscopists from observation on post mortem staining. This lipoid substance, having an affinity for the coloring matter used thus, is to be seen most plainly where most abundant. It seems to me no direct observation could be more illustrative of the process I have deduced from my own observation on the behavior of the tonsillar epithelium combined with the correlation I have shown to exist between this and other activities of the living organism.

Much has been written of the behavior of drops of fluid of various chemical constitution when brought into contact one with another. Such artificial liquid cells, by virtue of their surface tensions, exhibit phenomena of exchange of material, of change of form, and of segmentation closely analogous with those of living cells.

In other places I have referred10 to the experiments of Lippman and others, especially of Leduc.

To try to ignore the important bearing these observations have upon vital processes is childish. Wilhelm Roux, the great expositor of mechanical principles applied to vital processes, has taken the matter up" in some observations he has made upon the forces set up on the surface of a drop of chloroform immersed in a carbolic acid solution. When drops of each come within the radius of mutual attraction and repulsion one is reminded not only of the influences existing between conjugating cells, but of the forces exhibited within the cell in the process of mitotic division. Of course, it is only a vague symbol, in its simplicity, of the enormously complex interplay between two colloid drops.

So large a number of observers have detected movements inside the nuclei of cells intra vitam that we are constrained to believe that these are constantly going on. It is difficult to regard such movements as passive. Indeed I do not see how this term can be properly defined or its meaning conceived under such conditions. We must regard it as due to change in the tension of the nuclear structure, as Heidenhain admits.12

We have just seen the reference Albrecht has made to the presence and influence of the globules

thermore there be if a hencelrift, 1004. Nos a and 2. I square again, from Dr. Rosenkam's article (2). "With regard to the biological position of the lipids, we can infer from their general occurrence that they are of fundamental importance for the living organization."

of a lipoid substance in the epithelial tissue of frogs. He arrived at this conclusion from methods of observation and in fields of scientific activity quite independent of those biological studies of nuclear changes to which I shall subsequently refer. I shall there attempt to show that in all likelihood it is the interrelation of these submicroscopic emulsion drops of lipoid or colloid which creates the movements and presents the pictures of intracellular mitosis and of other internal states of the cell. It is necessary to realize that the same process is going on outside of the cell in the lymph spaces and forms the condition of the circulation in the connective tissue. For here, as Albrecht insists, there are in reality no free spaces which communicate in every direction. The bursting and coalescence of these froth bubbles which consist of a lipoid coating, a sort of film formation, makes a very much coarser froth outside than Bütschli declares is the structure inside of cells, but we may see here shadowed forth, somewhat dimly it may be, not only the interchange between the cell and its environment, but possibly the origin of the intercellular substance, the fluid protoplasmic juice which fills these spaces.

I think it is clear that the distinction of the forces governing these lipoid bubbles depends on the difference in the chemical constitution of their surfaces, and the same may be said of the bacteria among them and of the dust particles. With the protoplasmic particles it is a difference of chemical constitution so subtle and so labile that it defies analysis; and evidently so minute are the divisions of matter that the terms chemical and physical lose their distinction. The fixation, the adsorption, the "complement" here we see is a dynamic one, apparently identical with forces we know as electromagnetic. Heidenhain, in referring to the coloring experiments of Ehrlich, probably had in mind this conception. He introduced basic aniline colors into the circulation, and it was observed that the nerve tissue alone, rich in lecithin and other lipoid substances, took up the stain, but not in the same degree in all organs. This distinction in the stain adsorption of basic compounds is known to depend on the difference in the alkalescence of the tissues, whence it was concluded that in the nervous system according to location and function, a gradation of many degrees of alkalescence is present. Combining this with the more recent experiments of Loeb whereby the alkalescence was shown to be dependent on nerve stimuli, I think the thread of connection between various vital phenomena becomes quite apparent, in view of the exposition I have ventured upon. But this is a conviction which cannot be derived from any one form of exposition however logical it may seem to the expositor. Let us therefore proceed to restate it from other points of view even at the expense of considerable reiteration.

A precipitation or sedimentation of ultramicroscopic dust on the surface of the bubbles, as Greig Smith has suggested for the bodies of bacteria, resulting from chemical or electrochemical action, may alter the degree or the sign of their surface tension and thereby alter the course of events. In the existence of the phenomena of agglutination and precipitation, as witnessed in the persistent work on

immunity we receive another intimation of the importance of a physical view of vital processes. Precipitation of insoluble dust upon the bacteria or the cell or upon the ultramicroscopic bubbles which compose them, or of new atoms upon an already complex molecule, creates a new dynamic equation, one of whose varying integral factors is the mass of the particle. This may be a very faulty way of expressing my meaning from a mathematical point of view, but it will serve to identify the influence of one common factor in vital processes and in simpler chemical actions.

Moore and Roaf18 have shown the affinities of the cells other than the red blood cells, for potassium and the phosphates and the lack of it for sodium and the chlorides. This distinction they ascribe not to the cell membrane, but to the internal mechanism of the cell; that is, the currents back and forth do not obey such osmotic laws as we have been able to deduce from the action of membranes on fluids outside of the body. They find there is a point of equilibrium, not identical with that of equal saturation, beyond which these attractive forces do not act. The cell by selective action draws to itself a large number of potassium and a small number of sodium ions, and there is an index of saturation for each, varying somewhat in different situations and under varying conditions. We have seen the indications of the same law governing the bacterium at the surface, the same equilibrium has been pointed out" for the tonsillar crypt, as for the liver cell and the kidney cell bathed in the fluids of their environments. The living colloid of the kidney cell acting on the inert crystalline molecule of potassium acts differently through its membrane than water through a dead membrane. The inert crystalline molecule of potassium and the dust particle have different sorts of tension from the white blood cell and the bacterium. The potential index of the surface tension therefore depends on the internal chemistry of the particle. One is very simple and the other enormously complex. But it also depends on its mass, its size.

Through observation by ultramicroscopy on the physical states of the colloid solutions of the metals, but especially through the remarkable mathematical demonstrations of Professor J. J. Thomson in his Corpuscular Theory of Matter we have become familiar with the electric energy on the surface of minute divisions of matter setting at defiance the law of gravitation. Whether, like the smile on the cat, the electric charge persists after the matter has disappeared it is not for us to say until the physicists have all come to that way of thinking. What we may gain from this most abstruse of investigations is a realization that the charge dominates ultramicroscopic bits of matter with rapidly increasing completeness, the more minute they are.

But we may receive another hint from Thomson's work. It seems probable that the corpuscles, whatever they are, carry the charge of electricity from atom to atom in solids just as ions act as vehicles of the convection of electricity in fluids.

¹³Biochemical Journal, January 22, 1908

¹⁴Wright, Medical News, March 14, 1905

[&]quot;Zsigmondi: Zur Erkentniss der Celleite.

It has been shown by chemists that changes of color in some of the benzol compounds, as exhibited by spectrum analysis, probably are due to the vibration of some of the atoms from one combination in the molecule to another, a sort of intramolecular pulsation, owing to some very slight change in the environment. This results in the changing of color without the destruction of the molecule. By a shifting of an atom or a group of atoms, which may be a very complex group, the ether is set to vibrating to a different tune, and our retina sends a different impress to the brain. Much of this apparently goes on in the "living" molecule.

The reaction of colloids to kataphoresis is highly significant when taken in connection with this pul-

sation of the benzol molecule.

"One colloid (for example that of a metallic sulphide or that of certain of the oxides) goes to the cathode and is therefore negatively charged (in relation to the water in which they are suspended). Others such as those of the hydroxides of the high atomic metals are positive and go to the anode. A third class finally, when in an entirely pure condition are nonelectric but take, in the presence of acids or alkalies, respectively a positive or a negative charge. It is amphoter. To this class belong albumin and gelatin." We see at once that a very slight change in the environment of a cell might set up an important physiological change in the protoplasm, and the return to its previous condition would constitute that oscillatory vibration upon which depends the manifestations of life.

It is impossible to advance very far into the secrets of immunity and infection without assuming this mechanicobiological standpoint. It is desirable in conformity with the subtitle of this paper to point out how delicate may be the chemical change wrought by a nerve current whereby the surface tension is affected and a different relationship established between a bacterium and a contiguous human cell, and also to indicate how this function

is connected with that of cell division.

44 WEST FORTY-NINTH STREET.

THE UROLOGICAL DEPARTMENT OF THE GER-MAN DISPENSARY,

· Including the Report of the First Season's Activity.

By Frederic Bierhoff, M. D.,

New York,
Professor of Contourney and Veneral Diseases, New York
School of Clinical Medicine; Attending Surgeon, Urological
Distance Contourney, Dispersion, et

When the writer, in 1902, entered the German Dispensary, all cases of genitourinary diseases (they consisted chiefly of gonorrhea and stricture) were treated in the dermatological department, as is the custom in the majority of dispensaries in this city. The class in which the writer had the privilege of working was in charge of the late Dr. I. P. Oberndorfer, who was kind enough to turn over all cases of genitourinary diseases to the writer for treatment. There had never been any provision made in

the old dispensary building for a separate class in genitourinary diseases, and the writer was, therefore, compelled to make use of the only room which could be placed at his disposal—a very small, dark room, which had formerly been used as a dressing room for the patients of the dermatological department. The arrangements were, of necessity, of the most primitive sort, and the instrumentarium crude and limited.

Microscopical examinations of suspected secretions had to be made at the home of the writer, and whatever sterilization was necessary was made by means of a small gas burner and cake tin, in the already all too small and stuffy room. When the German Dispensary left its old home in Second avenue, all of its wealth of clinical material was turned over to its successor there, the Deutsche Poliklinik. When it moved into its present quarters, the department of urology was still a subdivision of the dermatological department, and was given one of the rooms set aside for this department, which, it was thought, would be sufficiently large to meet all requirements. At first it was, too, as a completely new clientèle had to be built up. As time has passed, however, and the work of the department has grown, it has been found that more room was required, and a second room adjoining the firstone which is used by the dermatological department for its x ray work—has been placed at the disposal of the urological department when not in use by the dermatological. With the growth of the material and the sharper drawing of lines, the urological department has demonstrated, from the character of its material, that it is in no way related to the dermatological, and since about the first of the present year the two departments have been separated, and the urological now exists as an entity, as it should.

Scope of the urological department: In outlining the work of the urological department, those in charge have aimed to make it not merely a department for the treatment of venereal diseases, but rather one which embraces the diagnosis and treatment of all of the diseases affecting the genitourinary organs, both in males and females. Syphilis and chancroid have been relegated to the dermatological department, where they belong; gonorrhea and its complications and sequelæ to the care of the urological department. In taking up the consideration of the conduct of the urological department the methods will be considered which have been in use in the writer's class during the past year; or, to be more exact, from March 17, 1907, on which date the dispensary was opened, to December 31st.

The main ideas concerning the purposes served by a clinic for the treatment of genitourinary diseases which have been kept in view have been: (1) The treatment of the patients. (2) The keeping of statistics as accurately as possible. (3) Experimentation and research where possible and necessary. (4) Teaching. (5) The instruction of the

patients themselves.

In the management of any clinic, the writer believes that the aim should be not the treatment of the greatest number of cases in a routine manner, but the thorough, conscientious, and scientific treatment of those patients who present themselves in other words, not to try to make a record with re-

gard to the *number* of cases treated, but to try to get results for the patients. In order to do these things certain requirements present themselves, which must be met as completely as possible.

First: There should be a sufficient amount of room placed at the disposal of such a clinic, so that there may be no crowding, and no lack of space and ventilation, and that the utensils and the appliances which are needed may have a place, without encroaching upon the space necessary for proper work.

Second: There must be a sufficient number of assistants to permit of each branch of the work being

done thoroughly and systematically.

Third: In doing the work the aim should be to do it as well and thoroughly as possible, without, however, encroaching unnecessarily upon the working

time of the patients.

Rooms: There should be two adjoining rooms, one for the examination and treatment of such cases as may be of an infectious nature, and a second for the examination and treatment of such as are not infectious, or such as require the use of special instruments, or appliances, and for the examination and treatment of females and children. In the German Dispensary we have arranged it so that in one room the ordinary treatment is carried out, particularly of those patients with gonorrhea, or its complications, while the other room is reserved, so far as possible, for endoscopies, cystoscopies, dilatations, the use of the psychrophore, for electrical treatment, and for females and children. Both rooms must have proper light and ventilation, and should have a sink with running hot and cold water. In the room in which the routine work is performed, and into which the patients should enter from the waiting room, there should be a desk at which the records and histories are taken; next, a table for the microscope; third, a sink with sloping shelf to provide for the proper draining of glasses, etc.; fourth, a sterilizer sufficiently large to permit of the sterilization of the catheters, sounds, etc.; fifth, an operating chair or table; sixth, a stand containing basins for the various solutions in ordinary use; seventh, an instrument cabinet to contain the instruments in ordinary use; eighth, shelves containing the stock solutions, reagents, etc. Furthermore, hooks for the patients' clothing. The second room should contain, in addition to the sink, an operating table, an instrument cabinet for the examining instruments, such as the cystoscope, endoscope, and electrical instruments, a glass topped table or two, and a wall cabinet containing the electric controllers, rheostats, etc. There should, in addition, be an arrangement with the pathological laboratory to make the uranalyses, and the more intricate bacteriological examinations and culture experiments.

Assistants: For the proper carrying out of a comprehensive scheme of management of a clinic of this character one chief and at least four assistants are required. The chief, who should be a man properly equipped in the special study of genitourinary diseases, must be in general charge of the clinic, and should personally see to or superintend the examination of each new case which presents itself. The first assistant should assume the treatment, under the chief's direction, of all the old cases, and

represent him during his absence. The second assistant should be kept for the purpose of rendering general assistance to both chief and first assistant when required. The third assistant should be at the microscope, and the fourth in charge of the records. The plan followed in the writer's class has been to allow the assistants to rotate monthly in the positions as outlined above. Each new month the assistant who has been in charge of the old cases during the preceding month takes the records. second assistant thereupon takes the place vacated by the first assistant. The third, who was at the microscope, takes the general assistantship, and the assistant who was at the records takes the microscope. In this way each assistant is repeatedly brought into direct contact with each branch of the work, and is made familiar therewith. The assistants should be required to pledge themselves to serve for at least six months, with the understanding that, if their services prove satisfactory, they will be appointed for the subsequent six months.

Examinations: It has been our custom to make a microscopical examination of the discharge in every case presenting itself for examination, at the first visit, and, in case of gonorrheal infections, to microscopically control the secretions at each subsequent visit, until the patient is discharged as cured, or withdraws from treatment. With nongonorrhœal cases the examinations are made until such a time as the secretion is found to be free of bacteria, after which the examinations are not necessarily made at each visit. Any change in condition, however, which appears in the slightest degree suspicious brings with it a microscopical examination. Where a suspicion exists that the prostate is involved, the secretion of the prostate is taken after a previous total irrigation of the urethra, and examined, both with regard to its cellular and its bacterial contents. Should it be found abnormal in any respect it is regularly examined at each visit, until it is found to be free of bacteria, and, later, at less frequent intervals, until it is found to be normal in every respect. This, naturally, entails a large amount of work upon the assistant who is at the microscope, but as he has no other duties it is found to be easily possible for him to make the necessary examinations at each session. Where any doubt exists concerning the infectious or noninfectious character of the secretions, the patient is instructed to stop all treatment until the question shall have been definitely decided. It is our hope in future to be able also to add the examination of urines, where necessary, to the microscopical work already undertaken.

Records: The taking of records is, as stated before, the exclusive work of one assistant. The patient, upon entering the room, if for the first time, steps up to the desk and is given his division card, bearing a number which corresponds to the number upon his history card. The usual questions must be asked and entered, and a superficial examination made by the assistant in charge of the records, for the purpose of making a clinical diagnosis, preparatory to a more exact examination. The form of history card in use at the German Dispensary is as shown here. The purpose of such records should be not only to obtain a correct history of the case

itself, but also to gather accurate statistics, as will be shown by a glance at the card. The card is reproduced in English, although, as our histories are kept in the German language, it is printed in German.

History card.

Experimentation and research: Each assistant should choose a topic for study, and follow this up carefully, with the idea of publishing the results, and for that purpose all cases coming under the heading of his particular topic for study, should be specially referred to him. Where no topic is chosen, the chief should suggest, or assign one to each assistant, and help, where necessary, in the working out of the study. Each article, before being sent out for publication, should be revised by the chief, and the institution should receive its due credit.

New methods, new drugs, etc., should be thoroughly tested, in an unbiased manner, and the re-

sults published.

Teaching, and the instruction of the patient: Wherever possible, the courtesies of such a clinic should be extended, without charge, to such physicians as may wish to study the methods for the diagnosis and treatment of diseases of the urogenital tract. Furthermore, if the chief, or any one of the assistants should chance to occupy a teaching position in a medical school, it should be his privilege to invite his students to visit the institution. In other words, wherever it is possible safely to do so, the clinical material should be utilized for the purpose of teaching the assistants, or out-

In the teaching of the patient, another side of the possibilities for good of a clinic presents itself. Patients who frequent dispensaries do not come for a sermon on morals, or a tract, but for the quickest possible relief of their physical ailments. who come for the treatment of diseases other than venereal, need no sermons, and upon the venereal patient they are usually lost. It is easy enough to pose as a reformer, from the depths of an armchair, but an entirely different matter to attempt to bring about a reform without being able to suggest an equivalent, or the means for betterment. The rational means for the prevention of venereal diseases seems to be marriage. But the struggling workman, who has often a hard task to keep his own soul and body together, cannot conscientiously enter into matrimony until his wages allow this. He has, however, sexual desires, and is, in a large percentage of cases, of a somewhat stunted moral development. He, therefore, seeks the only relief

of these desires open to him—the public prostitute. It has struck me, during years of service, in various dispensaries, that an appeal to the moral sense of the average dispensary patient, is wasted time and effort. His first consideration is, naturally enough, himself, and it can only be through fear of the effects upon himself, with the consequent loss of the ability to "hold his job," that we may hope to influence the venereal patient. I have often been disagreeably surprised at the callousness shown by the average dispensary patient, with regard to the danger of transmission of his disease to others. Still, we have tried to impress our patients with the fact that they are criminals who, while knowing themselves to be venereally diseased, indulge in intercourse; furthermore, that they must not consider themselves cured until pronounced so, at the dispensary. In order to lend weight to our arguments, we have had printed, in German and English, the following leaflet for free distribution:

GERMAN DISPENSARY,

(Dermatological Department)

Park Avenue and 76th St., New York. GENERAL DIRECTIONS FOR PATIENTS SUFFERING WITH GONORRHOEA.

I. You are suffering with a contagious disease. You must, therefore, be careful to carry out the orders of your doctor exactly, in order that the danger to yourself may be made as little as possible, and the infection of others prevented.

II. Complications develop very easily, during the course of this disease, particularly after sexual intercourse, or sexual excitement, or after drinking beer, wine, or liquors.

III. The absence of a profuse discharge does not mean that the infectious stage of the disease is past. Even in the watery discharge, or in the threads in the urine, the germs may live for a long time after all acute symptoms are gone, thus making it still possible to infect others. Therefore do not consider yourself cured until the doctor tells you so definitely.

IV. Should you, for any reason, have to remain away from treat.

IV. Should you, for any reason, have to remain away from treatment here, then go to some reputable physician, or dispensary, for treatment; tell him the nature of your illness, and follow his instructions until he tells you that you are cured. Never consult "quacks" or these doctors who advertise.

V. Do not resume sexual intercourse until the doctor tells you that you are cured. If you ask the doctors, they will inform you how to avoid infection.

RULES TO BE OBSERVED.

1. After every handling of the parts, do not forget at once to wash the hands well, with soap and water, and to dry them upon a clean towel. Keep this towel separate, for yourself.

2. Do not touch or rub your eyes. The danger of infecting them is very great, and may lead to blindress.

3. Wosh the diseased parts gently, morning and evening, with lukewarm water and soap, drying with a small piece of clean, soft linen (such as part of an old handkerchief). Burn the cloth after using. Sleep alone.

4. The doctors will show you how to apply a small dressing to protect your clothing from the discharge. Wear one of these con-

Take at least one warm, full bath a week, just before g ed. Wear the protective dressing during the bath. After wash out the bath-tub with soap and water.

6. Dress yourself warmly; avoid draughts, exposure to cold and et, and wet feet. Keep as quiet as your work allows. Keep the

Do not touch beer, wine, or liquor at all. Do not drink car-bonated waters. Drink plenty of plain water, or milk. Coffee, or tea, in small quantity, will not be injurious.

8. Avoid spices, such as pepper, mustard, paprika, cloves, cinnamon, nutmeg, or foods containing them. Eat plain, light food. 9. Avoid the company of women. Sexual excitement brings on amply that

10. Come regularly for treatment, and carry out your treatment at home carefully. When in doubt ask the doctors.

We also warn them against the dangers of promiscuous intercourse, and add that, if at any time, they have the least suspicion of any venereal infection, they must not delay, but come to us at once for examination. We have, therefore, abstained from suggesting the "coitus condomatus test," preferring to rely upon the alcohol test, and that of control examinations for a period following the disappearance of gonococci from discharge and shreds.

We believe that we can best limit the spread of venereal diseases by thoroughly curing our patients.

Routine of work: The routine of work, as we have found it to be most satisfactory, and least time consuming, has been as follows: The patient enters the room and reports to the assistant at the desk, giving his card bearing his history number. The history card is then consulted, and the patient's present condition noted, any changes being entered under the proper date. If discharge is present, the patient passes to the assistant in charge of the microscope, who, thereupon, takes the customary smear, by means of a sterilized platinum loop, and marks the specimen with the patient's card number for examination. After this the patient passes his urine into two glasses, all but the last few teaspoonsfuls into the first glass, the rest into the second, and shows this to the assistant at the records, for his inspection. We have found that this method fully suffices for the determination of the question of the involvement of the prostate in the inflammatory process. Its condition is noted upon the history, and reported to the assistant having the treatment in charge. Whatever changes are present are reported to the chief, who outlines any changes in treatment which he may deem necessary. During this time usually the microscopist has had a chance to examine and report upon the specimen. The treatment is then carried out as required by the case. Should the men in charge of the treatment be busy, the patient awaits his turn until they are at leisure, and the report is thereupon given to them. In the case of new patients, the examination is made by the chief, or by an assistant under his direction. The more complicated examinations, such as endoscopy, cystoscopy, etc., are made by the chief, or by one of his assistants under his supervision, and it has been our custom to demonstrate every point, or condition of interest, to all the assistants.

Treatment: Gonorrheal cases have been treated by means of irrigations and injections. For the past several years we have employed (as a test) the solution of the salicylate of mercury, a report of which experiments will be published separately. Irrigations are made with the hand syringe of 150 c.c. capacity. Where the anterior urethra alone is involved, the irrigations are not forced through the compressor muscle, and the anterior urethra alone is irrigated. During the course of a gonorrhœa, the patients visit the dispensary every second day, for treatment. The patients are instructed how to properly inject themselves at home, four to five times daily, and are given the necessary instructions with regard to diet, care of themselves, etc. The irrigations and injections are continued until the discharge has been found to be free of gonococci for at least a week, whereupon the frequency of the injections by the patients themselves is gradually diminished, and the quantity and strength of the irrigations cut down. Should the discharge remain free of gonococci, and gradually disappear, the patient, after a reasonable period of freedom from discharge containing gonococci, is subjected to the alcohol test. Should shreds remain in the urine, these are examined, to determine their freedom from gonococci; then an endoscopy is made, and the remaining pathological changes locally treated by dilatations, as-

tringent injections and irrigations, local applications through the endoscope, etc. Should gonococci reappear after the cessation of injections, then an endoscopy is performed and the diseased points located, the infected glands slit up, and the irrigating dilator of Kollmann employed, or the glands are destroyed by electrolysis. Should the second urine at any time be found to be cloudy, then a total irrigation is made, the patient is instructed to empty the bladder of the irrigating fluid, and the prostatic secretion is gently expressed and immediately examined. After this, another total irrigation is employed. Should gonococci be found to be present, then the total irrigating and the massage of the prostate are continued until the prostatic secretion becomes normal and free of gonococci, and the second urine perfectly clear. Should the compressor muscle offer resistance to the easy injection of the irrigating fluid, then it is anæsthetized by means of the injection of a weak solution of cocaine (one half to one per cent.). Should complications such as spermatocystitis, or epididymitis arise, then, in the absence of febrile reaction, the irrigations are continued and the massage also, this, however, being little more than a slight, gentle pressure, to express the superficial layers of infected secretion. compresses are applied to the inflamed epididymis, the compresses being covered with a layer of oiled muslin or silk, suspension being made by means of the Teufel suspensory. The patients are instructed to remain in bed between visits, and, should their condition not permit this, are referred to the hospital for treatment during the acute stage. After the subsidence of the acute stage, the treatment, as before outlined, is carried on.

No instrumentation whatever of the urethra is permitted in any case, whether gonorrheal or non-gonorrheal (with the single exception of the irrigating dilator), without a preliminary irrigation of the urethra with an antiseptic solution. All instruments are sterilized before use, those which can be boiled, by boiling; cystoscopes and similar instruments by immersion in formalin, alcohol and water solution. All instrumentation is followed by another irrigation with an antiseptic solution. Furthermore, it has been our custom, as a routine measure, to put patients who were subjected to instrumentation, under the internal use of one of the formaldehyde compounds.

Vesical cases are never treated without first having been subjected to a cystoscopical examination, in order to determine the exact condition, irrespective of the symptoms.

Cases which come under the general heading of sexual neurasthenia, are never treated until after a thorough examination has been made, both of the prostate, seminal vesicles, and the urethral canal, for we have found that, in the majority of instances, the neurasthenia is simply the expression of a palpable change at some point of the genital tract.

During our first year of service in the new dispensary (in reality only nine and a half months) the number of our patients has, necessarily, been small. This has been due to the facts first, that the clientèle which we had in the old dispensary had been lost to us, because of the fact that an interval of one year had elapsed between the closing of the

old and the opening of the new dispensary, and second, by its location in a district which is already, in great measure, covered by other well known hospitals and dispensaries. We have had, therefore, to build up an entire new clientèle, against rather heavy odds. In spite of this fact, however, the class has steadily grown. The total number of patients treated in the writer's class, was 173, the total number of visits 1,489.

We, as also other dispensaries, have found trouble in getting patients to come to us until we could pronounce them *definitely* cured, for, with the working man, the absence of a visible discharge seems enough to constitute a cure for him. This is not to be wondered at, for the absence from his work, which attendance at a dispensary entails, often means the loss of his position and the means of his livelihood. We have always tried, therefore, to have patients return for treatment only as often as the character of the case absolutely demanded. A gratifying feature to the writer has been the fact that a fair percentage of the cases coming to us have remained with us until we could definitely pronounce them cured, or, at least, until their condition was such that the gonococci had disappeared and the cases were clinically well.

⁵³ EAST FIFTY EIGHTH STREET.

THE FIRST AMERICAN MEDICAL SCHOOL.*

By James J. Walsh, M. D., Ph.D., LL.D.,

New York,

Dean and Professor of Nervous Diseases and of the History of Medicine at Fordham University School of Medicine.

In recent years there has been a growing interest in the history of medicine here in America. Physicians have not had more leisure, but have cared to devote time that used to be given to reading what had no connection with their professional or scientific work, to the story of how the development of present day medicine has come about. This is especially true for times that make epochs in medical education, because it is realized that the uplift of the medical profession of this country depends to a greater extent on the education which physicians obtain than on any other factor. Here in America it has usually been presumed that the history of medical education dates back to only a little before the foundation of our government. Recent interest in Spanish American affairs, however, has shown that important additions to the history of medical education on this continent, proving that it extends back for nearly four centuries, should be made.

Our medical histories ordinarily announce that the first courses in medicine were delivered in Philadelphia in 1765 by Dr. Morgan and Dr. Shippen. During the next five years by the addition of other professors this became a complete medical school. Nearly two centuries before this, however, according to one of the chroniclers in 1578, according to another in 1580, a chair of medicine was established at the University of Mexico. This university had been given a charter more than a quarter of a century before, in 1551, the same year that a charter was also granted by the Spanish crown to the University of Lima in Peru. Its first courses were not given, however, until 1553. Chairs in the arts and philosophy and law and theology were established at once. The chair in medicine did not come for a quarter of a century, though there had been some interest in medical education before this. doctors in medicine whose studies had been made at universities in Spain were received at the University of Mexico within two years after its foundation-in 1554. In the city of Mexico itself there were a number of educated physicians from Spain at this time, and indeed the first book ever published in medicine in this country was published in the city of Mexico in 1570. Its title was Opera Medicinalia, by Francisco Bravo. Another book, Secretos de Chirurgia, had been written in this country by Dr. Pedrarias de Benavides, and was published at Valladolid in Spain in 1567.

With all this of interest in medicine in Mexico it is not surprising that a chair of medicine should be established and that a series of professorships should gradually be established in connection with it until there was a complete medical school in our modern sense of the term. We still have the names of all the professors who occupied the principal chair of medicine at the University of Mexico from the end of the sixteenth down to the nineteenth century. Flores, in his History of Medicine in

Mexico from the Time of the Indians down to the Present Day, tells the story of the rise and progress of this Mexican medical school, the first on the American continent. The first professor of medicine was Juan de la Fuente, a graduate of the University of Salamanca, who was considered one of the distinguished medical scholars of the time. The inaugural lecture according to one good authority was delivered June 21, 1578. The salary of the professor in medicine was paid partly by the Viceroy of Mexico and partly by the crown of Spain. We usually do not think of Philip II who occupied the Spanish throne at this time as a liberal patron of education, but such he was for the Spanish colonists. This is one of the surprises of Philip's character that has been brought out by recent historians.

As a matter of fact the Spanish colonies encouraged by the Spanish home government, very early in their history developed certain features of scientific education and professional life that were not to come in English America until several centuries later. On Columbus's second expedition there was a Doctor Chança who had been physician in ordinary to the King and Queen of Spain and who joined the expedition as a sort of scientific attaché. On his return he wrote a volume of scientific observations that he had made in America many of which as might be expected related to medicine. Dr. Ybarra, of New York, has recently published a brief résumé of this first book containing scientific observations with regard to America in the Journal of the American Medical Association. Early in the sixteenth century the Spanish writers published volumes on the habits and customs and folk lore of the Indians and especially on Indian medical practice. It is usually supposed that the anthropology and ethnology of the Indians only developed in the nineteenth century, but there are many important books on these subjects published in Spain and the Spanish colonies in the sixteenth and seventeenth centuries.

It is not surprising then, to find that even the establishment of this chair of medicine in the University of Mexico in 1578, was not the first organized effort to teach at least the practical side of medicine that was made under the Spanish régime. Within a few years after the establishment of the city of Mexico a definite attempt was made to give such medical training (even though a full medical course was impossible) as would enable both the colonists and the natives to have the benefit of trained skill at least for the cares of wounds and injuries of various kinds. By a decree of the Ayuntamiento or Council of the Viceroy, issued January 13, 1525, more than half a century before the foundation of the chair of medicine, a barber surgeon was voted a salary to teach his art to others so that there might be some training for those who wished to care for the injured, or those in need of surgical assistance. It would remind one very much of our public lectures on First Aid to the Injured, and yet it probably included much more of medical science as it was then taught than we give in these courses.

^{*}Paper read at the semiannual meeting of the Faculty of Ford ham University School of Medicine, 1908.

¹Historia de la medicina en Mexico des de la epoca de les Indios hasta la presente. Por Francisco Flores. Mexico, 1886

The first teacher in this department was Francisco de Soto who bore an honored name, though this is

all that we know of him.

According to Flores there was not long afterward some medical teaching of a more ambitious character at the College of Santa Cruz in Tlaltelolco. This was a special quarter of the city of Mexico mainly inhabited by Indians in which a school for the benefit of the natives was established in 1536. At this school were trained many of those who afterwards became alcaldes and other officials of the native villages in the neighborhood of Mexico. In general the college seems to have been established with the idea of training natives who might occupy official posts of various kinds under the Spanish colonial government, yet closely in connection with the natives. It was felt that such men would rule their fellows much more understandingly than a foreigner could. One means of enabling the young men thus trained to get the confidence of their native subjects was to give them a sufficient knowledge of the elements of medicine to enable them to care for the natives whenever a regular physician could not be obtained. The teaching of medicine was done by regular physicians of the city, graduates of Salamanca and Valladolid, who had emigrated to Mexico and who were paid for this purpose by the Spanish authorities.

Five years after the foundation of the first chair in medicine-in 1583-a lectureship in this subject meant to provide some subsidiary instruction was added. It was not until 1598 that a second professorship in medicine was established and a division of the teaching made. To this second professor was entrusted the teaching of the principles of therapeutics. A chair of botany had been founded in connection with the university about the same time as the first professorship in medicine was added, and medical students were supposed to take prolonged courses in this subject. In 1583 dissections were begun, though this subject was not taught exclusively for the benefit of the medical students. It was not easy to procure bodies at this time, and much of the dissection was done on animals, and students from other departments of the university shared in the instruction. Before the end of the sixteenth century, however, human dissections began to be regularly done. Another set of subjects that the medical student was expected to take, is of interest to us because of the change of view in the matter that has come. This was the department of mathematics and astrology the lectures of which medical students were expected to attend, because the stars were still supposed to have an influence on human constitutions, and the doctor was supposed to tell something about his patients' illness and its possible prognosis by consulting the stars.

Of course it seems very foolish to us that astrology should have maintained a hold for so long on rational intelligencies but it must not be forgotten that at this time and even later men like Galileo and Kepler still firmly believed in astrology as the science of the influence of the stars on worldly events and especially on men's lives. At least they were quite willing to accept handsome remuneration for the horoscopes which they drew up for wealthy and rocal chem. Their astroprognostic got many a jolt, however, and perhaps never more so than when

Galileo made the horoscope of his friend the Grand Duke of Tuscany while he was ill, and announced that he would live for many years and accomplish many glorious things, though he died twenty days later. We have so many suspicious things behind the thin glass of our houses at the present time from uric acid to the latest fashionable remedy which will be given up next year, that it would seem better for us not to throw stones at the show cases of the earnest serious students of the sixteenth century, who undoubtedly were mistaken in their acceptance of the influence of the stars on human life and destiny, but who at least made this an excuse for the study of the sciences of mathematics and astronomy which cannot have been without a good influence.

A review of the subjects of study in the medical school of the University of Mexico at this time is of interest. A brief but comprehensive review of the course is given in Flores's History already quoted. It is all the more interesting because it was practically a replica of the teaching at the University of Salamanca at this time. It was founded almost entirely on Hippocrates's teachings though the study of Galen was only second to that of the great Greek father of medicine. This devotion to the ancients may at once condemn it as hopelessly unprogressive in the minds of certain overmodern physicians, but it must not be forgotten that at the end of this same century—we are talking of the beginning of the seventeenth century-Sydenham in England (the English Hippocrates) and a little later Boerhaave in Holland whom we are accustomed to look upon as distinguished influences in medicine and to whom we owe much that is precious of incentive to clinical observation and who were themselves magnificent observers, declared that the study of Hippocrates is "most profitable to physicians," and insisted that his writings should occupy much of the student's time and the practitioner's spare hours.

but if the Mexican professors of medicine were at all like Boerhaave and Sydenham then they neither attached themselves nor their students so exclusively to Hippocrates as to nullify personal observation. The course outlined is not only interesting and suggestive but it gives a very good idea of the comprehensive view that the physicians of the time took of the details of medical education. In the first year the students were required to take up Hippocrates's treatises De Elementis, De Temperamentis, De Humoribus, De Anatomia, De Facultatibus Nativis, and De Pulsibus et Urinis. This portion of the curriculum included the consideration of all the underlying conditions of disease as far as they were known at the time. There was besides an introduction to pathology, for all diseases were supposed to be due to the humors of the body. Whenever we are inclined to make little of the lack of progressiveness of old time physicians, it is as well to recall that the humoral pathology which was taught at that time is still popular pathology. Virchow declared shortly before his death that the idea of cellular pathology had never made any headway among the people. People are still bilious or their blood is poor or they have a catarrh, in a word there is something the matter with some humor or

secretion of their body. Even physicians in talking

Hippocrates constituted the basis of the lectures,

to patients still have to revert to this old fashioned terminology in order to make themselves understood, though it is doubtful whether in doing so

they do not do more harm than good.

Of course all of this first year work was mere book learning. Anatomy was taught from books, and there was very little objective about the teaching. In this respect it must not be forgotten that objective medical teaching except for human anatomy which came in the second year in Mexico is a comparatively recent introduction to our American medical schools. In taking up Hippocrates's Treatise on the Pulse and the Urine there was perhaps some practical applications of the propositions set down, but in general this first year's work seems to have been the theoretical introduction that our lecture system of a half a century ago provided for medical students during the nineteenth century.

In the second year the teaching became more practical and objective, though theoretical questions still occupied much of their attention. In this year they studied Hippocrotes's treatises De Differentiis Febrium, De Arte Curativa, and De Sanguinis Missione, that is they learned to distinguish fevers from one another from printed descriptions of them, learned the theoretical basis of therapeutics, and discussed the indications for bloodletting. During this year special attention was paid to human anatomy. They had to do dissection, though most of it was on animals. At this time the pig, whose internal organs resemble very closely those of human beings in many respects, was a favorite subject for dissection in the medical school. They had to at least attend demonstrations on the human cadaver and every one was expected to have seen the dissection of at least two human subjects.

In the third year they studied the Aphorisms of Hippocrates and his book Quos et quando oportet purgari and the Ninth Book of Rhazes. The Aphorisms of Hippocrates are practical remarks with regard to disease, the connections of symptoms, methods of treatment and prognostics. Purgation as studied from the standpoint of Whom and When the Doctor Ought to Purge was an important subject at a time when they thought the most important thing in the world was to get the materies morbi out of the system either by bloodletting or through the emunctories. It is not surprising that Rhazes, the great Arabian physician, who practised at Bagdad in the tenth century should have been placed just next to Hippocrates, for Arabic influences were strong in Spain, and Rhazes eminently deserved the place given him. It may be recalled that he was the first one to give us a definite description of the smallpox and a distinction of measles. He has some excellent chapters on Diagnostics and Rational Therapeutics.

In the fourth year they returned to complete the study of Hippocrates's Aphorisms and devoted considerable time to his De Crisibus and De Diebus Decretoriis, that is on the crises of diseases and the critical days of illnesses. It is not surprising that they should have thought so much of Hippocrates's Aphorisms. Every man in medicine whom we look back to as an authority and who did such work as to make his name and influence remembered, read Hippocrates's Aphorisms with delight, applied them

to his own cases, and usually commented on them for the benefit of others, not so much with the thought of adding anything to them as to making their application clear. This work was Paracelsus's favorite reading, and though he condemned over devotion to the classics of medicine, he wrote a commentary on it. It was one of Sydenham's favorite volumes, and Boerhaave returned to it again and again and his largest work is a commentary on this of Hippocrates. Most part of the fourth year in medicine at the University of Mexico, however, was taken up with Galen's De Methodo Medendi, a very important contribution to therapeutics in its own time, whose significance founded on observation has never been quite lost. It has formed the favorite reading of leading physicians even in the last century or two.

Taken all in all the medical course of the University of Mexico thus arranged gave no mean introduction to the practice of medicine. At the beginning surgery was not admitted into the course and anatomy was studied only for medicinal purposes. The reason for this serious omission was the persistence of the old disagreement or schims as it may well be called between the physicians and surgeons. During the fourteenth century by a fatal degeneressence of opinion, internists thought it beneath their dignity to use the knife, and considered surgical intervention and manipulations as the work of handicraftmen. They passed over the doing of all operations to the barber surgeon, some of them even ostentatiously tying their hands behind their backs and directing the barber surgeon in his work. Surgery was for years taught as much apart from the medical schools as dentistry now is with us, and this old custom survived in Mexico. We have already seen that a special arrangement for the training of barber surgeons and their assistants had been made earlier in Mexican history and this doubtless continued. During the seventeenth century, however, human anatomy came to be studied with more zeal, and then surgery was introduced into the medical school on a footing only slightly lower than that of medicine.

The methods of examination are of interest to us especially at the present time when we are just about to hold our own. The examinations were held by public disputations. A series of propositions with regard to medical subjects was selected at the meeting of the faculty, and the candidate for a degree of doctor of medicine was expected to defend them. These propositions were posted publicly twenty-four hours before the disputation, or oposicion as it was called in Mexico, was to take place. When his turn came the medical student was expected to discuss one of the propositions and state what he knew about it. Various professors then objected to his presentation of the subject and suggested difficulties which he had to answer. His method of answering these constituted the material for the judgment as to whether he should pass the examination or not. His passing depended on a vote of the faculty which was all present. The examination of each man occupied an hour and sometimes more. Such an examination after all as enabling the faculty to judge of the character of a man's intelligence and to realize just how he tackled

a question and responded to difficulties, some of which at least he would not have anticipated, is not such a bad way of estimating the depth and solidity of a man's education, and might be considered by some people preferable to the written methods which may include more, yet often only encourage

cramming for examinations. The preliminary education required for admittance to the medical school is of interest at the present moment when this subject is to come up for special discussion at this meeting of the faculty. Students were only allowed to enter the medical school after having made studies in the undergraduate department and completed at least three years. The medical student had to know Latin well, for all the textbooks of medicine of the time were written in this language. Some studies in botony, in mineralogy, and in climatology were included in the undergraduate course so that there was some preparation for their medical studies. In general, however, they had to study logic, grammar mainly Latin, rhetoric, mathematics, and philosophy. This latter included some psychology, general and special, the Spanish psychologists being the leaders of thought in their subject at this time, and metaphy-

The noteworthy fact, however, was that a man had to spend seven years at the university before he received the degree of doctor of medicine. We are gradually getting to the position where we will require this again. It is amazing to think that with standards like this set so long ago we should have degenerated to that condition of medical education in America which characterized the middle of the nineteenth century. Fortunately we are on the upward swing of the pendulum in medical education, and the outlook is most hopeful.

110 WEST SEVENTY-FOURTH STREET.

THE STOMACH AND INTESTINAL GASES.

With a Description of an Apparatus for their Collection and Analysis.*

By Seymour Basch, M. D., New York,

Attending Physician to the German Poliklinik, Department of Discases of the Stomach.

The important rôle which they play in a number of abnormal conditions lends to the study of the stomach and intestinal gases a more than theoretical interest. As is well known, the alimentary canal, after the very first ingestion of food, is never entirely free from gases. Throughout life there is a constant cycle of production and elimination. Under healthy conditions this interchange proceeds without discomfort or marked disturbance, but, if from any cause there is a derangement of its equilibrium, flatulence, borborygmi, meteorism, tympanitis, and other conditions, varying in their significance from merest discomfort to severest gravity, will result.

I. THE STOMACH GASES.

The gases which occur in the stomach have been the subject of extended investigation. Much has been learned of their nature and of the conditions under which they are produced. Complete lists of these investigations are given in the various textbooks. Notwithstanding all that has been studied and written, the profession in general has shown but little interest in the subject.

This is mainly due to the apparent lack of direct clinical value of such knowledge and to the absence, heretofore, of a simple apparatus for the collection and analysis of these gases. The inverted test tube and the Fiebig fermentation tube can be used for qualitative, but not for quantitative, estimations. Hoppe-Seyler's adaptation of the Woulff bottle (1), while simple enough to be used clinically, permits a large proportion of carbon dioxide to be absorbed by the water in the bottle, and thus renders an exact quantitative analysis impossible.

The apparatus to be hereinafter described is intended both for the collection and the analysis of stomach and intestinal gases. In its construction and its manipulation it is sufficiently simple to be used wherever ordinary clinical laboratory facilities may be had.

The varieties and sources of gases found in the stomach are:

1. Oxygen and nitrogen, from air swallowed with or independently of eating and drinking. Most of the air which enters the stomach is gotten rid of by eructation. Nothnagel (2) states that free oxygen is never present in the lower bowel.

2. Carbonic acid gas, nitrogen, sulphuretted hydrogen, ammonia, and other gases contained in food stuffs, beverages, medicated liquids, and mineral waters

3. Gases originating within the stomach itself. In the early stages of normal gastric digestion, microorganisms may cause fermentation and the development of carbon dioxide and hydrogen. Miller (3) states that this ceases as soon as a large amount of free hydrochloric acid has been produced. Schierbeck (4) has shown that during digestion carbon dioxide is generated by the secreting cells of the gastric glands. Strauss (5) and Rosenheim (6) found ammonia present in very small quantities. Under pathological conditions, such as ulcerating carcinoma, abscess of the stomach wall, stagnation of stomach contents, etc., besides these gases, sulphuretted hydrogen, marsh gas, and other hydrocarbons may be formed.

As a contribution to the study of stomach and intestinal gas formation, I wish briefly to cite the results of some of my own analyses with the apparatus to be later described. These analyses were made a few years ago in the laboratory of Professor Zuntz, of Berlin, the clinical material being obtained through the courtesy of Dr. H. Strauss from Professor Senator's division at the Charité. While the series is by no means an extensive one, the results serve to demonstrate the practical applicability of the apparatus, and to show the relative proportion in which the gases found occurred.

Stomach Cases.

These were three in number, viz., I, gastric carcinoma (with pyloric stenosis, palpable tumor, stagnation of contents, lactic acid, strong butyric acid odor, etc.); 2, benign stenosis of the pylorus (no tumor, but retention of contents and, generally, free

^{*}Re I is part with a demonstration of the apparatus used at the annual scrom of the American Government of Association, At lanta City force a 1997

¹⁸Stomach contents obtained on afternoon of the same day as No 5, the gas percentages here are almost identical with those of atmospheric air.

¹⁸Nations not further determined as a portion of the apparatus became disarranged.

hydrochloric, but occasionally, lactic acids); and 3, a perigastric abscess communicating with the stomach. The diagnosis in this case was confirmed by autopsy. The stomach contents of this patient were always purulent, and had the foul odor of decompo-

sition; lactic acid was constantly present.

In these three cases, thirteen gas analyses in all were made. The contents were always obtained by aspiration into a pear shaped bottle, by a method later to be described. Whenever free gases were drawn out with the stomach contents they were analyzed as soon as possible; otherwise, the collection apparatus was placed into the thermostat and the gases that were formed determined later. The individual analyses are detailed in the following table:

From these few cases general conclusions cannot be drawn. The results, however, suffice to illustrate the kind and proportions of gases that were formed from the fermentation of the gastric contents both inside and outside of the stomach in the

three cases under observation.

Reviewing the table, we note, in the first instance, that sufficient free gas was usually present for immediate analysis. Only rarely was it necessary to resort to fermentation in the thermostat. After their withdrawal for analysis, the stomach contents were several times (see table) placed in the thermostat for a varying period, and the gases that developed were also examined.

There was a very marked difference between the percentage of carbonic acid gas in the early (introgastric) and the later (thermostatic) gas mixtures. Analyses I and 2 were exceptions in this respect, but even in these, the artificially fermented stomach contents yielded more carbonic acid gas than was

obtained directly from the stomach.

Notable, too, was the entire absence of marsh gas in twelve out of the thirteen analyses; in the exceptional case (No. 13), it formed but 0.8 per cent. of the entire gas mixture, and may have resulted from pus decomposition. Hoppe-Seyler (1), who analyzed eleven cases of gastric dilatation, both malignant and benign, never found more than the merest traces of this and other hydrocarbons present. On the other hand, McNaught (7) reported 6.8 per cent. and Kuhn (8) 8.9 per cent. and 9.31 per cent. in cases of benign pylorus stenosis with ectasia, Ewald (9), 2.7 per cent. and Frerich (10), 10.75 per cent. With but few exceptions, the diet and the time of the last meal and of the last gastric lavage, if any, were not stated.

Hydrogen, on the contrary, was present five times out of eight, in the freshly obtained contents, and three times out of four, after thermostatic decomposition. Its amount varied from 0.8 per cent. to 16.4 per cent. Both Hoppe-Seyler (1) and Kuhn (11) found this gas very frequently present in cases of gastric stagnation. With other investigators they agree that its formation is largely due to butyric acid fermentation. Hoppe-Seyler found that a proteid diet greatly diminished, and a mixed or a carbohydrate diet increased the amount of hydrogen

present.

The rather large percentages of oxygen in the fresh's expressed contents may be due to the swallowing of air by the patient. It was present in much

larger proportions in the fresh contents than it was after thermostatic fermentation.

With one exception, sulphuretted hydrogen was always absent. This exception, like that of marsh gas, occurred in analysis 13, and it, too, may have resulted from pus decomposition. It was not present either in the freshly obtained contents nor after twenty-four hours' exposure in the thermostat. It developed only after much longer decomposition. This constant absence of sulphuretted hydrogen in our cases is, after all, not surprising, in view of the results published by Boas (12) and Zawadzki (13). As a result of numerous observations, Boas states that sulphuretted hydrogen is very frequently present in benign gastrectasias with free hydrochloric acid, that have received little or no treatment, while it is extremely rare in malignant gastrectasias, where lactic acid, etc., occurs. Sticker (14) who also investigated this subject, ascribes the occurrence of sulphuretted hydrogen in the stomach, in most instances, not to albuminous food decomposition, but to diastatic action of the salivary juices upon certain sulphur containing oils present in common kitchen herbs. He concludes that this gas has a diagnostic value only when such herbs are excluded from the

In a number of cases no gases were generated by the stomach contents, even after being kept several days in the thermostat. The stomach contents of the patients here reported, and of a number of others, were at times left as long as two weeks and over with negative results in this respect. Similar experiences with normal stomach contents are mentioned by Riegel (15) and others, but none as far as I can learn have been reported with the contents of patients with gastric dilatation.

II. THE INTESTINAL GASES.

What are the sources and varieties of the intestinal gases? While Zuntz (16), Ruge (17), Tappeiner (18), Tacke (19), Planer (20), and others have made some investigations into the nature and origin of these gases, their researches have been limited to animals or to experimental deductions from examinations of the expired air. To the best of my knowledge, careful studies and investigations in the human being into the exact causes, place, and manner of development of the intestinal gases, as well as into the influence of dietetics, medication, physiological measures, etc., upon them, have not been made or published. Hence, while we have some positive knowledge, much that is stated in the textbooks, and of what follows here, is purely deductive and theoretical.

The gases found in the intestinal tract are derived from the following three sources: I, They enter the bowels from the stomach; 2, they pass into it by diffusion from the blood; 3, they are formed within the gut itself. This last is the most important

source.

I. The gases that enter the bowel from the stomach may be any or all of those already mentioned as occurring in the latter organ.

2. Nitrogen, according to Bunge (21), and carbon dioxide, according to Nothnagel (2), pass into the intestinal lumen by diffusion from the blood.

3. Most of the intestinal gases, however, are

formed in the bowel, and this production of gases takes place more or less constantly through fermentation, bacterial decomposition, and, in the upper part of the small intestine, through the chemical decomposition of the alkaline carbonates of the pancreatic, biliary, and intestinal secretions by the acid chyme and the fatty acids: Gas production is liveliest where there is active fermentation, and slowest where putrefactive changes and inspissation of fæcal contents occur. Generally speaking, therefore, the greatest amount of gas is formed in the upper portion of the small intestine, less so in the lower, and little or none in the large intestine. A marked exception to this rule is found in conditions of hyperperistalsis without obstruction. Here the contents are rushed through so rapidly that gas formation is practically uniform throughout the entire gut.

It is obvious that the nature, quantity, quality, and preparation of the food, and the digestive activity of the alimentary secretions are influential factors in the production of gases. Under ideal conditions of food preparation, ingestion, and digestion, the kind and quantity of gases will vary greatly from those arising under abnormal conditions.

The carbohydrates yield hydrogen, carbon dioxide, marsh gas, and other hydrocarbons, the last named group of gases varying in amount in inverse ratio to the digestibility of the carbohydrate. Ruge (17), Tappeiner (18), and Planer (20) have shown that those rich in cellulose yield more hydrocarbons than does any other variety of food. Since cellulose is resistant to the gastrointestinal secretions of man, the production of marsh gas and similar compounds must be the result of bacterial action. Carbohydrates rich in starch and poor in cellulose yield little hydrocarbon, but much carbonic acid

The proteids develop relatively less carbonic acid gas than the carbohydrates, but, they yield, in addition, hydrogen, marsh gas, nitrogen, ammonia, and sulphuretted hydrogen, and, under certain conditions, nitrogen. Ruge (17) has shown that under a pure meat diet, the intestinal gases of man contain very large amounts of marsh gas (26.45 per cent.).

It was formerly held that the greater part of the intestinal gases passed out by the anus. This view is now known to have been erroneous, and it is conceded that in the healthy individual, at least, as much disappears through absorption into the blood and expulsion by the respiratory tract. This is proved by the fact that, although gases are formed continuously in the healthy individual, little or none escapes through eructation or by the anus, while the condition of intestinal distension remains pretty constant. Consequently, a large part must be absorbed, and escape by way of the lungs. This has been proved by experiment. Thus Tacke (19), with rabbits in Zuntz's laboratory, found that in these animals ten to twenty times as much of the intestinal gases escapes through the lungs as per anus. The ratio for human beings is not known.

The formation and elimination of these intestinal gases are intimately associated with body metabolism. Under normal conditions the study of these processes has only theoretical interest. When, however, there is an overproduction or a difficulty in

their elimination, clinical conditions that may be associated with the gravest consequences to the patient may result.

Abnormally large amounts of gas in the bowel may result from causes disassociated with the integrity of that organ. Among these are the swallowing of excessive quantities of air, or perhaps, too, of carbonated beverages. In the latter case, the gas is usually gotten rid of by eructation. The passage of gaseous material of any kind from the stomach into the bowel may give rise to intestinal flatulence.

The condition known as "aerophagy" (air swallowing) is met with in very rapid eaters and drinkers, as well as in certain nervous individuals who are adepts at autoinflation. At times, very marked abdominal distention is produced. Such conditions of extreme distension have been most often observed in hysterical individuals. The occurrence is sudden, frequently without apparent cause, but usually is associated with some exciting or depressing psychic influence. It has been observed to occur with menstruation or after childbirth. The condition may last only for a few hours, or it may continue for weeks, and then disappear suddenly. Its disappearance may be spontaneousthe result of a new psychic influence. The cause of this distension has not been definitely determined, but the most accepted explanation is that of Valentier, viz., an hysterical paralysis of the intestinal muscular system. This would account for the sudden onset and disappearance. The gas very probably escapes (noiselessly) by the anus, though its reabsorption into the blood is regarded by some as the cause of its disappearance. The gas is said to be odorless, but so far as I can learn its exact nature has not been examined into.

Certain foods, when subjected to bacterial, yeast, or other fungoid action, yield large amounts of gases. To mention a few, we have those containing organic acids as sour wines, mayonnaises, pickles, fruits (especially overripe); those rich in cellulose as cabbages and legumes; those giving starchy fermentation products as certain varieties of bread, pastry, etc. In some persons, milk causes much gas.

The pathological stomach conditions which contribute to excessive intestinal gas accumulation have already been mentioned.

Diminished elimination of gases is caused by obstruction to their escape by the anus, or by interference with their absorption through the bowel wall. Obstruction to their escape by the anus is met with in the various forms of intestinal obstruction, and in atonic or paretic conditions of the muscularis. Interference with gas absorption through the bowel wall results from any cause that produces stasis of the blood circulation. Such causes may be general ones, as general peritonitis, severe acute fevers (especially in enfeebled persons), obstruction to the portal circulation, etc., or they may be local, as in some forms of intestinal obstruction (volvulus, kinking, intussusception, etc.). Gas elimination is rendered much more difficult, when, in addition to the congestion, there is excessive gas production through fermentation or decomposition of the intestinal contents.

Intestinal Cases.

These numbered six in all, and in them a series of twelve gas analyses were made, details of which are shown in Table II.

CASE I.—Chronic recurrent dysentery (nonamœbic). Patient had very many, for the most part liquid and semisolid, greenish or brownish moderate sized passages, usually acid in reaction, and mixed with blood and mucus. The diet at the time was a mixed one, consisting daily of three rolls, two eggs, some oatmeal gruel, small amount of milk, mashed potatoes, beef soup, veal, and some rice, farina, etc. The faces showed good meat and starch digestion, but potato cells were always present. Two analyses of gases, obtained on separate days, directly from the rectum, showed respectively:

a. CO₂, 4.1 per cent.; O, 8.4 per cent.; CH₄, absent; H, 8.4 per cent.; N, 79.1 per cent.; and H₂S, absent.

b. CO_2 , 3.5 per cent.; O, 18.4 per cent.; CH_a, 5.1 per cent.; H, 0.4 per cent.; N, 72.6 per cent.; and H_2S , absent.

These two specimens of gases, obtained directly from the rectum, reveal the presence of very little carbon dioxide (about 4 per cent.), of 0.4 per cent. and 8.4 per cent. hydrogen, of 5.1 per cent. marsh gas in one instance, and its total absence in the other. The presence of oxygen apparently contradicts the statement of Nothnagel (2) that this gas is never found free in the rectum. It is, however, very difficult to collect sufficient gas from the human rectum for analysis, and it is probable that there was some air in the rectal tube that was used. More examinations will be necessary to definitely settle this point.

The further analyses in this patient, as well as in

TABLE II.—THE GASES OF FÆCAL FERMENTATION

| | | TABLE II.—THE GAS | SES OF FÆCAL | FERMENTATION. | |
|---|---------------------|--|-------------------------|--|---|
| Clinical diagnosis. | Analysis number. | Material used and its preparation for analysis. | Volume of gas analyzed. | Composition of gas mixture. | Daily diet. |
| 1. R. Chionic recur- ient dysentery | 1 | single, semisolid acid stool; kept sixteen hours in thermostat, | 46.384 cc., | CO ₂ , 87.1% O, 1.0% H, 5.0% CH ₄ , absent, N, 6.9% | mixed (3 rolls, 2 eggs, oatmeal gruel, mashed po- tatoes, 200 cc. bouillon with farina, carrots, cel- ery root, etc., I litre milk, |
| | 2 | single, semisolid, acid stool; kept sixteen hours in thermostat, | 34.54 C.C., | H ₂ S, absent, CO ₂ , 90.9% Q, 0.8% H, absent, CH ₄ , absent, N, 8.3% H ₂ S, absent, | and 40 grammes butter. |
| | 3 | mixture of six liquid and semisolid stools, all of one day; kept twenty-four hours in thermostat, | 51.844 c.c., | H ₂ S, absent, CO ₂ , 91.8% O, 1.4% H, 1.2% CH ₄ , 0.3% N, 5.3% H ₂ S, strong, | ditto. |
| | 4 | material of analysis No. 3; kept seven days longer in the room, then twenty-four hours in thermostat, | 10.575 c.c., | H ₂ S, strong, CO ₂ , 70.5% O, absent, H, 4.2% CH ₄ , absent, N, 25.3% H ₂ S, strong, | ditto. |
| II. Z. Intestinal tu- berculosis (?); ad- vanced pulmonary tu- berculosis with diar- rhœa | | single, liquid, mucous stool, acid reaction; kept twenty-four hours in ther- mostat, | 20.46 c.c., | H ₂ S, strong, CO ₂ , 44.6% O, 2.16% H, 25.9% CH ₄ , 0.14% N ₁ 27.2% H ₂ S, trace, | Darmdiät. ⁶ |
| III. J. Pulmonary tuberculosis (no special bowel symptoms) | | single, well formed, alka- line stool; twenty-four hours in thermostat, | 11.861 c.c., | H25, trace, CO2, 49.8% O, 3.9% H, absent, CH4, absent, N, 46.3% H25, trace, | Darmdiät. |
| IV. S. Reconvales- cence from acute peri- carditis.4 | | Single, thick, pasty, acid stool, twenty-four hours in thermostat; very rapid gas formation, | 52.42 C.C. | CO ₂ , 93.8% O, 1.6% H ₂ S, very strong, ⁷ , | Darmdiät. |
| | | single, liquid, acid stool; kept twenty-four hours in thermostat; very slow gas formation, | 18.388 c.c., | CO ₂ , 59.6% O, 3.2% H, 3.0% CH ₄ , absent, N, 34.2% H ₂ S, absent, | ditto. |
| | 9 | material of analysis 8, kept three days in room, then four more in the thermostat, | 34.192 C.C., | CO ₂ , 75.8% O, 0.7% H, 4.9% CH ₄ , 2.1% N, 16.5% | ditto. |
| | 10 | material of analyses 8 and o, kept nine days longer in the thermostat, | 12.059 € €., | H ₂ S, absent, CO ₂ , 53.8% O ₂ , 2.8% H ₁ , 21.4% CH ₄ , 6.9% N, 15.1% | ditto. |
| V. S. Chronic consti- pation and chronic ar- ticular rheumatism | | single, well formed, alka- line stool, kept twenty- four hours in thermostat, | 14.52 c.c., | H ₂ S, very strong, CO ₂ , 62.6% O, 6.1% II, 2.0% CH ₄ , 0.2% N, 29.1% | ditto. |
| VI. S. Chronic alcoholism | | single, partly pasty, partly liquid stool, | 14.06 c.c., | H ₂ S, very strong, CO ₂ , 66,3% (O ₂ , 66,3% (I, 7.0% H, absent, CH ₄ , absent, N ₂ 20.7°, Il ₂ S, strong, | mixed, full. |

⁴This patient had no subjective symptoms, but daily had several light brownish yellow evacuations, usually acid in reaction, and varying from a fluid to a thick pasty consistency. They were always full of gas bubbles, and microscopically showed numerous fatty acid crystals.

acid crystals.

Determined by strips of liber paper moistened with lead acetate solution.

Most of these analyses were made while I was engaged in the investigation (23) of A. Schmidt's Gührungsprobe (24), and the patients, at a time, were under a modification of his secalled Homodal, viz.: 3 /wichack, a cage, 25 grammes of wheat flour, 45 grammes of oatmeal cooked with 10 grammes of sugar, 50 grammes mashed potatoes, 530 c.c. bouillon and 1,600 c.c. of milk.

Too little gas mixture left to determine the other gases.

the others, were not made from gases taken directly from the rectum, but from the gaseous products of fæcal fermentation outside of the body. The fæces, after being placed in an apparatus to be later described, were allowed to remain in a thermostat at 98.6° F., and the resulting gas mixture analyzed. While not identical with gas formation within the intestinal tract itself, the gaseous mixture resulting from the placing of freshly passed fæces in a brood oven under total exclusion of air, if properly interpreted, will, no doubt, disclose important data regarding the fermentation and putrefactive processes within the intestines (22).

In all, a series of twelve gas analyses were made. The details of these are shown in the following

table:

If we now briefly review these analyses, a few

facts will be noted:

We find that under a mixed diet, the largest part of the gases consists of carbon dioxide. amount, naturally, is larger under a full than under a light diet. This is illustrated by the patient of Case IV, where the figures are 93.8 per cent. for an average mixed diet, and but 59.6 per cent. for the much lighter Darmdiät. As might be anticipated, rapidity of peristalsis is an important factor. Thus, Case I (chronic dysentery), under a light mixed diet, gave 91 per cent. carbon dioxide, while Case III, with no special intestinal symptoms, under practically the same character of diet, gave but 49.8 per cent., and Case V (constipated at the time of the investigation), where the patient had a much heavier mixed diet, yielded only 62.6 per cent. of carbon dioxide. It would seem, therefore, that the longer the ingesta are retained in the intestine, the less carbon dioxide are they likely to produce. Carbonic acid gas being a product of fermentation, is most abundantly evolved in the earlier stages of intestinal decomposition, whereas the hydrocarbon series, being the result of putrefactive decomposi-tion, develop, in general, later. The findings in Case IV offer a good example. After three days in the thermostat, there was present 75.8 per cent. carbon dioxide, and no marsh gas; after nine days more the carbon dioxide diminished to 53.8 per cent., while the marsh gas increased to 6.9 per cent. These results agree with those of Tappeiner (18), who has studied gas formation in the intestines of cattle.

As the fermentative changes are replaced by the putrefactive, sulphuretted hydrogen also increases. Contrary to the prevailing impression, it is normally present in but small amount in both intestines and faces, the familiar odor being due mainly to skatol, and, to a lesser degree, to indol and the fatty acids.

It should be noted also that gas mixtures did not always result from placing of the fæces within the thermostat. Thus, once 50 grammes of fæces from patient of Case VI generated but 5 c.c. gases after twelve hours, and no more at all up to 286 hours; one specimen from patient of Case I yielded no gas up to five days, though, as a rule, the stools of this patient were frothy, and gave large quantities of gas. A third patient, 40 grammes of whose fæces were left in the thermostat, yielded 3 c. c. in ten hours, and no more gas up to 200 hours. Similar results were obtained in a number of other instances.

but these few suffice to show that sometimes little or no gas can be obtained from thermostatic fermentation of intestinal excreta.

(To be concluded.)

ELECTROTHERAPEUTICS.

Its Relation to General Medicince, Its Indications and Results from Its Use.*

> By Mulford K. Fisher, M. D., Philadelphia,

Assistant Instructor in Electrotherareutics; Assistant Demonstrator of Pharmacy, Medicochrurgical College.

A title as comprehensive as the one I have given to this paper may well cause a smile of derision, that the writer may be presumptuous enough within the narrow confines of a single paper to attempt to cover a field so pregnant with meaning as this title would indicate. However, it is not the intention to do more than glimmer a few thoughts in this recently developed and rapidly expanding field of therapeutics; to convey to you a few only of the possibilities that electricity presents in the treatment of disease; at the same time avoiding as much as possible technical expressions and endeavoring to present an entrancing subject in such a manner that the few thoughts here presented may be readily understood.

The genius of the present day has made electricity the attribute of its power. Mysterious, alluring, symbolic of the magician's wand, it girdles the earth, carrying messages quicker than the winged Mercury of old; it turns night into day; it prints our books; it dissolves bodies into their constituent elements; it carries our audible voice to the listener hundreds and perhaps thousands of miles away; and yet though conscious of its laws, although harnessed by the genius of civilized man into doing for him the mighty marvels which the past century has witnessed, yet the true nature of electricity is unknown. From the days of the Hindu god Indra, the god of Thunder; from Jupiter, who waved his thunderbolt over trembling Rome; from the Phœnicians, the mariners, who brought the amber from which they thought the hidden principle of life was derived and from which the name electricity is derivated (amber being called electron): while students were taught to read the will of the gods in the lightning of the skies; while scientists, priests, and philosophers labored to deciper this superhuman and shadowy mystery, down to the present day of the wizards Edison and Tesla, this element which lives in the skies, connects the material with the spiritual, obedient though it be to the will and wish of man, has eluded and baffled all who have worked and struggled to uncover its real identity.

It is indeed deplorable from the standpoint of the physician that we know so little of the real nature of electricity. From the days of Galvani, who by an accident came upon that form of electricity which bears his name, this natural agent has had its periods of ebb and flow. At first vaunted as a cure all, by which the blind could be made to see; the dumb to speak; the lame to throw aside their

^{*}Address delivered before the Mount Sinai Hospital Ex-Presidents' Association, July 2, 1908.

crutches and walk, it later sank into oblivion and was only practised by charlatans and quacks. As new discoveries were made and physicians commenced to learn the true indications and more important still, the limitations of this agent in the diagnosis and treatment of disease it again has come into repute, and the vast strides which electrotherapeutics has but recently made makes us sanguine that the day is not far distant when every student of medicine may be taught the underlying principles and become skilled in the manipulations of the necessary apparatus for the application of one of the most valuable therapeutic agents at his command.

The various forms of electricity which are employed are too well known to need more than passing comment. They are first, the static or frictional. (and in America we have made the greatest strides in the perfection of the induction machine); secondly, the galvanic or constant; third, the faradaic, or interrupted; and fourth, the high frequency. It is impossible to take up here a discussion of the various apparatus, which may be employed for the carrying out of any of these methods. The numerous manufacturers of electric appliances are only too anxious to demonstrate and proclaim the particular merits of their machines.

As physicians, what relation should we bear to electrotherapeutics, or rather should electrotherapeutics bear to us? Should we as some near sighted medical men have done and still continue to do, utterly decry its usefulness, or at the other extreme use it indiscriminately in the treatment of every form of bodily ailment? Fortunately there is a happy medium between the two, and in order to render the allegations urged more tenable, it may be wise to make a casual résumé of some of the physiological actions, or perhaps speaking more properly, the pharmacology, of this mysterious force upon the human body.

Chief among these may be mentioned the tonic effect of electricity. If there is one potent agent in addition to the usual hygienic measures of fresh air, sunshine, pure food, and bathing at our command in the treatment of functional debility, or exhaustion, it is electricity. I have seen the most marvelous results from the application of static electricity, particularly in cases of nerve tire or exhaustion, and it would be folly in view of the lack of a neurotic element in many of these cases to assert the success to be due to the psychic factor alone.

Secondly, its stimulatory action is so well known, particularly in cases of degeneration of muscles and nerve, as to require no more than passing mention. In paralyses of various forms electricity is often the only agent which seems, if not to arrest the course of a progressive disease with its accompanying loss of motion or sensation, to at least give to the diseased muscle or nerve some tone and to stay often for an indefinite time the further inroads of an incurable lesion.

Another property, and one which up to the present time little use of has been made in a practical way, is the increased elimination which electricity may cause. Carefully made experiments by patient observers have proved conclusively that there is a decided increase in the amount of urea exercted:

that carbon dioxide elimination is markedly increased; and it is a matter of common observation that patients while undergoing treatment or for some time after their séance is over, frequently have most drenching sweats.

The absorbing action of electricity, its power to relieve congestions or stagnations, due of course to its action on the vascular and lymphatic systems, is another property of its practical use that has been made in medicine. Exudates are absorbed; fibrous deposits disorganized; excessive callus at the site of fractures dissolved; and in innumerable ways have we been able to derive pronounced benefit by electrical measures alone.

Another property which is of decided practical value is the sedative influence of electricity. Many patients will tell you that they can always fall asleep almost immediately after a treatment, and how calming and soothing a static breeze may be only requires a self demonstration to convince yourself of this valuable adjunct in the treatment of highly wrought nervous or mental conditions. Time and time again have I been told by patients troubled with insomnia that the first application of electricity has given them the first night of untroubled sleep they have had in weeks, and often months.

It would be useless to decry the psychic effect electricity exerts. In fact the assertion is urged by its opponents that it is only in those cases in which the hysterical element is present that electricity is of any benefit. Be that as it may (and it is not the province of this paper to controvert on any issue) it is well to know that if by suggestion we can alleviate human suffering it is not for us to decry the means by which it is accomplished.

Electrolysis is made use of in various ways, in the removal of nævi, warts, facial blemishes, moles, trichiasis, and in the cure of aneurysm.

Cataphoresis, the introduction of drugs into the body by electrical means has lately fallen into disuse, but a number of years ago remarkable results were recorded from its use in neuralgia, for the relief of local muscular spasms in superficial muscles, in rheumatic or gouty swellings, and to produce local areas of anæsthetization for cutaneous operation. In these cases the anodal, or positive electrode saturated with cocaine or some other local anæsthetic would be placed over the painful area, the indifferent electrode on the spine or at some other point of the body, and in a few minutes decided relief with insensibility of the affected part is experienced. That the current, in this case the galvanic, does cause the penetration of the drug into the body is proved by examining the urine of patients subjected to this procedure. It is found that the urine frequently shows traces of the drug which is used for cataphoresis, showing plainly its systemic dissemination.

Many of the failures in the treatment of disease by electrical measures can be ascribed to the failure to understand one or two simple principles. The underlying factor for electrotherapeutics is to understand and intelligently use your poles. Polarity is of the utmost importance and the properties, anodal and cathodal, may be summed up in a nut shell. The positive pole, or anode produces vasoconstriction, causes an increased flow of blood through the part; removes congestion and stagnations of any of the fluids of the body, and causes firm coagulation of blood. On the other hand the cathode or negative pole has just the opposite effect. It produces a dilatation of the blood vessels; it is dissolving and absorbent in action and causes destructive meta-

morphosis.

The knowledge of these principles forms a groundwork upon which we can build up our whole electrotherapeutic structure. A proper recognition of the patient's condition is therefore essential, and it is by knowing the results that it is desired to be attained, that we must discriminate in our use of the poles. For instance, a patient is to be given the static breeze for the relief of a headache. It is highly essential therefore, for the operator to know whether it is a headache due to anæmia, hyperæmia, or congestion. If due to anæmia, let us say, the treatment therefore is plain. The negative pole is grounded and the positive pole, which you now know induces an increase in blood flow is connected directly to the patient. Or again it is desired to cure a urethral stricture by electrolysis. Referring again to these rules we know that the proper urethral to use is the negative which is absorbent, softening, and destructive in action,

It would be equivalent to an encyclopædic rendition to even mention by name the conditions met with in general practice in which electricity has been found of service. The references previously made in this article may give some clue to the fields in which treatment by electrical measures may be instituted. And the specialist has not been backward in realizing the possibilities which electrotherapeutics offers. The ophthalmologist uses it with pronounced success in many cases of commencing optic atrophy; in opacities of the cornea or vitreous; in retinal hæmorrhages; in ptosis; contracted vision; amaurosis; and in numerous ocular defects; it is employed by the dermatologist often with most gratifying results when the usual local and systemic medications have failed; and since the researches of Apostoli, of Paris, with the wide publicity given to his treatment of uterine fibromata by galvanism, gynæcologists have found electricity of decided benefit ofttimes in dysmenorrhæa, amenorrhæa, engorgements of the uterus, and in cases of obscure pelvic disease where other treatment proved of no

To state that we have in this agent a cure all is one of the things most desirable to avoid, and it is best to stop the iteration of the therapeutic indications of electricity at this point lest I be judged ultraoptimistic. For this is one of the things which in the past has consigned electricity to be practised only by the quacks and charlatans. Even at the present time electricity is a therapeutic ashheap into which are piled the chronic ailments, the incurable diseases, the cases on which after the pharmacopæia has been exhausted, the internist disgustingly turns to the electrotherapeutist, says "Give him electricity," and washes his hands of the whole matter. And although frequently he is surprised to be encountered with an unlooked for cure, yet the failure to achieve a beneficial result often gives ground for an undeserved condemnation of a valuable therapeutic adjunct.

One thing not to be lightly passed over is that while electricity does not always cure, frequently disappoints, and is fallible to the same degree as other medical agents, yet of one thing we are assured: It never harms. And if this hasty sketch does nothing else but impress upon you this one point;—that, if in electricity, for the sake of hypothesis, we have not a measure which is of benefit in the treatment of disease, at least it does not prolong or aggravate the patient's ailment—this paper will not have been written in vain.

CONSERVATISM IN SURGERY OF THE HANDS.

By J. A. Hofheimer, M. D., New York,

Formerly Chief Surgeon, Out Patient Department of Harlem Hospital.

In these days of major operations the details of minor surgery are frequently disregarded by the ambitious surgeon, and in consequence it too often happens that fingers or hands have been amputated when these members may have been saved by patience and attention to minutiæ.

Notwithstanding the fact that many cases of traumatism to the hand appear very unpromising at the first visit, yet it is the surgeon's duty to be conservative and to attempt the salvation of every part of this member—ample opportunity is afforded in the future to amputate if absolutely necessary.

Frequently the injury is not seen until several days have elapsed since the accident and after the wound has been attended under home auspices or by some tyro in medicine. These patients generally have a complicating cellulitis or lymphangeitis, requiring discretion and care in order that further dangers may be avoided which could prove serious to life or limb.

Several years' experience in public and private practice has afforded the writer opportunity of noting many severe cases that were restored to their normal state. Citation of a few of them may elucidate:

CASE I.—Guy H., a young lad, while endeavoring to pick up an object from the ground, was struck upon the hand with a large rock thrown with considerable force by a playmate. The result of this blow was a compound fracture of the little finger at the third surgical phalanx, just above the metacarpophalangeal articulation. The soft parts were completely severed, excepting that there remained attached a small piece of integument on the outer side of finger, from which the member dangled.

The patient was brought to my office during my absence, and a nearby physician called in. He at once decided to complete the amputation by severing the attachment with scissors, declaring that the finger could not be saved. Happening to arrive at this juncture, after examination I decided to make effort toward saving the digit. The parts were well cleansed and refreshed by slight scraping of cut surfaces; the tendons were sewed with catgut and a series of interrupted sutures coapting the soft parts, the bone set and a splint applied. This was about one hour after the accident. Two days later the dressings were removed, and the wound found in a satisfactory condition and redressed. At the end of two weeks passive motion was begun, and the case soon discharged with perfect joint action and no deformity.

Case II.—Viola H. This little girl, while watching her mother at work using a clothes wringer, suddenly thrust her index finger between the cogs of the machine, thereby sustaining a compound comminuted fracture (contused and

lacerated) of the first and second phalanges. When first seen about half an hour after the accident the parts were swollen and the wound filled with clots and dirt from chewing tobacco which had been applied as a hæmostatic. The hand was gently bathed in warm bichloride solution and of bone were picked out with splinter forceps, the wound brought together without suture—a small vent for drainage being left at one side-and a splint applied. A slight slough occurred at one point, but at the end of three weeks the soft parts were entirely healed and the bone united. Passive motion soon lessened the rigidity of the joints and complete recovery followed, with no deformity.

CASE III.—Fred G., a young lad, about twelve years old, while endeavoring to drop from the top of a fence to the ground, became transfixed on a projecting spike, which penetrated through the skin and palmar fascia, catching beneath the outer tendons of the flexor sublimis digitorum. The boy hung thus suspended for a few minutes, when his weight and struggles proving too severe a strain for the muscular fibres to sustain, caused them to tear away in an irregular manner the full length of the muscular belly, pulling the torn tissues out of the wound in the hand at a

point midway between the ring and little fingers.

He was taken to a nearby dispensary, where the attendants voiced their intention of ablating the exposed muscular structures and closing the wound. Being called in consultation, the writer advised that an attempt should be made to save the muscle. Keeping the arm warm by wrapping it in hot, moist, sterile towels, the patient was removed to his home nearby. About one hour after accident, assisted by Dr. Remer and Dr. Stewart, the boy being anæsthetized, an incision was made from a point just above the folds of the wrist up to the middle of the forearm to the elbow, and a ' careful dissection made down to the point of muscular laceration, which was plainly discernible owing to the ecchi-moses along the torn fibres. After the seat of injury was disclosed a grooved director was passed through the lower channel in the annular ligament, under the palmar fascia and out through the initial wound in the hand. A silk filet was attached to the proximal ends of the torn muscles and passed through the eye of a stylet which was guided into the proper channel by the grooved director already in situ. This procedure permitted me to draw the muscular tissue by gentle traction back into the forearm without doing any by gentle traction back into the forearm without doing and further injury to the palmar fascia and avoiding danger to the palmar arches. The hand was forcibly flexed on the wrist to relax the muscles, and the torn parts sutured into position on both sides with catgut. The superficial muscles and fascia being replaced, the lips of the integument were horself to extend the city of the control of brought together with silk sutures. The original wound in hand was left open for drainage. Antiseptic dressings with short anterior and long posterior splints were applied, the posterior splint having a wedge shaped cushion placed under the hand to partially flex it; this cushion was grad-ually decreased in thickness at subsequent dressings, thus applying a graded tension on the muscle while in process of healing, thereby reducing chances of contracture. The following day the patient's temperature rose to 100° F., decreasing in another twenty-four hours, and remaining normal during balance of disability. The wound in arm healed by first intention; there was a slight slough at the point where the spike entered. The patient, now a young man, has complete use of his hand and arm, but presents a small contracture at the base of the ring finger, where slough oc-curred. This prevents complete extension of finger but does not affect flexion, and as the inconvenience is so slight he refuses to submit to a subcutaneous section of this band.

Case IV.—John W., twenty-five years of age, butcher. While endeavoring to use a meat chopping machine he caught his right hand in its interior and chopped off the thumb just above the metacarpophalangeal articulation, leaving the digit handing by a narrow palmar flap. This case was treated in a manner similar to case I with excel-

lent results, a normal finger being preserved.

CASE V.—Mr. V., æt. fifty, engineer. When first seen by me the patient had been ailing for over a week and complained of pains in his right shoulder, and a general febrile condition. He had been doctoring himself for rheumatism. Examination of the arm showed that it was swollen from hand to shoulder with numerous red streaks, a tubular lymphangeitis. Search for a possible point of entrance of infection disclosed at the base of the thumb about middle of the thenar eminence the remnant of what the patient

stated had been a "blood blister," which he had opened with his penknife. The man's hands were grimy with oil and adherent dirt; and all about the thumb, palm, and dorsum of the hand there was a boggy, indurated sensation, but no pain at this point was complained of. In the forearm, between the ulnar and radius, distinct fluctuation was noticeable, the glands at the elbow and in the axilla were slightly swollen. The patient was pale; heart sounds weak; rapid, small pulse; albuminous urine, and a temperature ranging from 102° to 104° F., with frequent chills. Blood poisoning being in evidence, an attempt to relieve the pus accumulations as quickly as possible was decided upon. Incisions were made at the point of original injury and in the forearm, evacuating considerable pus. Despite constant drainage, antiseptic moist dressings, and tonic treatment, the patient grew worse. Other pus foci formed, and numerous incisions were made to further their relief. A consultant advised me to amputate the hand above the wrist, as probing showed that the cancellous carpal bones were involved and the hand in a general sloughing condition. Feeling that more could be done toward saving the hand, I made several incisions on the dorsum between the metacarpal bones and also on the outer side of the fifth metacarpal. Into this latter incision a drainage tube was passed under the palmar fascia and through it the palm was irrigated daily, as were the dorsal wounds, with a solution of tincture of iodide, 5ii to pint, followed with several injections of hydrogen peroxide, and packed with aristol strips. An anchylosis throughout the hand persisted for over a month after the wounds healed, but this yielded to constant manipulation and frequent hot baths, the patient now having full restoration of function.

CASE VI.-Otto S., æt. twenty-eight. While aiding in placing a heavy machine upon a truck the middle finger of his left hand was crushed. He was first attended at an emergency hospital, where he was advised to have the finger amputated. The writer saw him about three hours later. At that time the finger was badly swollen, and split open as with a cleaver, the bone being chopped through longitudinally and the nail cut in twain and curled in between the fragments. The articular surface of the first phalanx was cut through, the soft parts badly lacerated and filled with dirt. An attempt had been made to bring the severed parts together by inserting two horsehair sutures on the palmar surface of finger, one of which did not hold, as the tissues were too friable. These sutures were removed, as I feared they would interfere with the circulation, already feeble from the crushing. After repeated cleansing with hot sterile water and hydrogen peroxide and removal of the nail, the finger was lightly bound with strips of aristol gauze and well wrapped in cotton for warmth, and a splint applied. This dressing was changed every fourth day, the strips being gradually wound tighter and strapped with zinc oxide plaster over the gauze as improvement advanced. By this means circulation was not restricted, and the strapping brought the parts into proper contour, besides acting as a splint to the fractured bone. Passive motion was performed at each dressing, and the finger eventually resumed its normal condition with perfect motion.

Usually it takes a little longer for these traumatisms to heal by conservative methods than after amputation. The explanation is simple. After an injury the crushing, bruising, and ofttimes infection causes a temporary destruction of the parts, these have to be cast off and new healthy growth encouraged; whereas in amputating the surgeon can select healthy tissues to operate upon, and first intention obtained thereby.

Very frequently the ambition and often the necessity of a patient compels him to return to work early, therefore he will not tolerate or thinks he is unable to afford a period of invalidism. This condition of affairs often urges upon a surgeon the performance of a radical operation, when a little patience could have saved the part, the gain in time to the client being given as an excuse.

Conservatism is a fundamental rule of good surgery no matter what portion of the body is involved. When to operate and when to withhold operation should aiways be the proposition most carefully weighed. Where there is the slightest chance of saving a part of the human economy endeavor should be made in that direction. Utility of a member is important to the wage earner, but a portion of a digit is better than none at all.

The cases here recorded are of sufficient frequency to illustrate the fact that a badly injured finger or hand is not in itself ample proof that amputation is necessary—give Nature a chance, and with proper aid many hopeless looking cases will gratify the attendant by their complete recovery.

Case V was a most unpromising one, tedious and exacting in its care; constant interference by friends and family, and great petulance on the part of the patient who certainly suffered greatly at times. He often begged me to amputate, and his case took nearly eight weeks to heal-but he has a useful hand and arm, and to a mechanic this means much.

Case III was an unusual injury, and in it fortunately no wound infection occurred. The avoidance of further injury to the palm of hand prevented a deformity as also did the gradual stretching of

the muscles during the healing process.

A characteristic of many patients is their inability to decide what is the best for them to do in a surgical procedure, and they will be impatient under the restraint of a protracted period of treatment. This is especially true about hand injuries and often leads to sacrifices where there should be none. While the surgeon seldom gets credit for his efforts in saving these small parts, it should still be his endeavor to conscientiously strive for conservatism where and when possible.

123 WEST 126TH STREET.

A CASE OF SPLENIC ANÆMIA. SPLENECTOMY. **BLOOD CHANGES.***

By I. HARRIS LEVY, Ph. B., M. D., Syracuse, N. Y.,

Associate Professor of Clinical Medicine, College of Medicine, Syracuse University; Visiting Physician to the Hospital of the Good Shepherd.

At the 1905 meeting of this society I reported two cases of chronic splenic anæmia occurring in twin sisters. One had already died from the disease. The other at that time was a chronic invalid. She has since had her spleen removed, and it is my purpose to place the case on record.

History: Miss M., Canadian, aged thirty-four. Father died at sixty-two of some stomach trouble; mother is alive and well at sixty-seven years of age. Three brothers and three sisters are living and in good health. One sister died at thirty-eight of peritonitis. Her twin sister died at twenty-nine of splenic anæmia. One brother, aged thirtyeight, living in Canada, is also beginning to show symptoms of this disease. Patient had the usual diseases of child-hood. From her fourteenth to her seventeenth year she was troubled with lumps or swellings about the size of a quarter, which would break out on the hands and feet. They were elevated, reddened, and would burn. In July, 1898, she had an attack of pleurisy with effusion. In September of the same year she had a severe attack of diarrhoea which lasted about four weeks. There was at the same time a great deal of soreness in the left hypochondriac region. The pain persisted for about three months and then disappeared. She then entered the Hospital of the Good Shepherd Training School for Nurses.

*Read by title at the annual meeting of the New York State Medical Society, January 30, 1908.

the work agreed with her. She gained in weight. Her color was good, and she was generally known as the "rosy

In January, 1898, she left the hospital to nurse her sister. In August of that year she had a second attack of soreness in the left side. Dr. W. L. Wallace examined her, but could find no apparent cause for it. The attack lasted some

weeks and then disappeared.

For the next two years she was in indifferent health. At times she felt fairly well and strong; at other times she felt run down and weak, and was forced to keep to her bed. felt run down and weak, and was forced to keep to her bed. In June, 1902, she again entered the hospital training school. The work proved too much for her, and, after being on duty for two weeks, she was forced to turn patient, suffering from swelling of the left knee, left elbow, and right large toe. The diagnosis of inflammatory rheumatism was made. After two months' illness she was able to leave the hospital. Change of scene brought about a marked improvement in her condition. About the middle of September she again undertook to nurse her sister. This she did until the latter's death, December 28th. She endured considerable physical as well as mental strain. Durdured considerable physical as well as mental strain. During 1903 her condition was poor. She was anæmic, had pains in the extremities, also in the left hypochondriac region. She had occasional attacks of diarrhœa. At other times she was constipated and suffered from sharp attacks of colic. She also had several attacks of stomatitis. The gums would become red and swollen. She also had a mild fever during the attacks.

In November, 1903, while visiting in Toronto, Canada, she consulted Dr. Cotton. He examined her, but could not determines any splenic enlargement. He found some thickening in the region of the appendix and advised an operation. This she declined, and returned to Syracuse.

Her condition again improved.

In February, 1904, she had an attack of quinsy. The convalescence was very slow. The soreness in the side continued. A blood examination made by Dr. Wallace showed hæmoglobin seventy per cent.; red blood corpuscles, 3,680.000; white blood corpuscles, 3,600; differential count, polymorphonuclears, 17.5 per cent.; lymphocytes, 46 per cent.; large mononuclears, 32.5 per cent.; eosinophiles,

In July she again visited Canada, and again consulted Dr. Cotton, and now, for the first time, he discovered that the Spleen was enlarged, and advised splenectomy.

In October she returned to Syracuse and consulted Dr. Wallace, who kindly referred her to me.

Examination, October 4, 1904: Patient was thin but not very anæmic. On the face there were a number of irregular brownish spots. The mucous membranes were of fairly

lar brownish spots. The mucous memoranes were of fairly good color. Tongue coated.

Lungs normal; heart not enlarged, sounds accentuated, but no murmurs. Pulse of moderate volume; some arrhythmia. The stomach did not reach below the navel. The liver dulness began at the fourth rib. The lower border was just palpable at the free border of the ribs, but was not enlarged.

The spleen was freely movable and extended three fin-ers' breadth below the free border of the ribs. It was

firm, smooth, and notched on its anterior border.

The right kidney was freely movable. The left kidney was also movable but to a lesser degree. None of the glands were enlarged. There was some tenderness over the sternum; none over the bones.

The blood examination showed a mild anamia of the chlorotic type. Hæmoglobin, 80 per cent.; red blood corpuscles, 4,800,000; white blood cells, 1,600. The differential count showed polynuclear neutrophiles, 13 per cent.; count showed polynuclear neutrophiles, I3 per cent.; large mononuclears, 40 per cent.; large mononuclears, 40 per cent.; eosinophiles, I per cent. No polkilocytosis; no nucleated reds, but some inequality in the size of the erythrocytes. Examination of the urine was negative.

A blood count made October 15th resulted: Hæmoglobin, 70 per cent.; red blood corpuscles, 4,700,000; white blood cells, 600. There were so few white cells that it was difficult to make a differential count. It was, however, very evident that the mononuclear cells far outnumbered the

polymorphonuclears.

On account of the frequent attacks of diarrhoa I determined to make an analysis of the stomach contents. She was given the ordinary Ewald test breakfast, consisting of 300 c.c. of water and 50 c.c. of bread, and the contents aspirated one hour later. The obtained contents formed a thick, gelatinous mass, consisting of much mucus mixed

with food particles. The bread was not well digested. A chemical examination revealed that free hydrochloric acid chemical examination revealed that free hydrochloric acid was entirley absent, the total acidity was four. There was neither pepsin nor rennet present. Two days later I gave her a test meal consisting of soup, meat, bread, and vegetables. Four hours afterward the contents were aspirated. The thick, gelatinous mass passed through the tube with difficulty. Macroscopically the various ingredients of the meal could be distinguished. An analysis gave the same result as before. No free hydrochloric acid no pensame result as before. No free hydrochloric acid, no pepsin, no rennet, and a small amount of combined acids.

During 1904 I made repeated examinations of the stomach contents at various times of the day and under varying conditions. The result was always the same—a complete absence of the free hydrochloric acid and the

Repeated blood examinations were also made. The red blood corpuscles varied from 4.100,000 to 4.800,000; the white cells from 600 to 2,700. The differential counts likewise gave similar results. The polymorphonuclear neutrophiles were always in the minority. The highest polymuclear count was 30 per cent.; the lowest 11 per cent. There was always a relative increase of the large mononuclear leucocytes. At no time were there any myelocytes or nucleated reds founds, nor was there any marked poikilocytosis. There was, however, some inequality in the size of the red blood corpuscles.

During 1905 and 1906 the patient was for the most part in Schenectady. Occasionally she would visit Syracuse. Her health was variable. At times she was quite comfortable and able to be about. Again she would have a relapse and would be forced to take to her bed.

Blood examinations were made at intervals, but there was very little change in the number of the white cells or in the

distinctive count.

In the Spring of 1907 her general condition was much worse. The anæmia was more pronounced. She suffered considerable pain in the left side. She was extremely emaciated, weighing but seventy-two pounds. It was evident that she would soon die of exhaustion unless relieved by surgery. The question of splenectomy had long been considered. The patient consented to the operation and entered the Hospital of the Good Shepherd for that purpose on July 4th last.

Examination at time of entrance: Patient very anæmic and emaciated. Lungs negative. Heart not enlarged. Hæmic systolic murmur. The spleen on deep inspiration Hæmic systolic murmur. The spleen on deep inspiration reached three inches below the free border of the ribs. Its surface was smooth and hard. Liver palpable but not enlarged. There was no ascites, nor enlarged glands. Blood: Hæmoglobin, 40 per cent.; red blood corpuscles, 3,000,000; white cells, 1,700. Differential count, polymorphoruclears, 28 per cent.; lymphocytes, 49 per cent.; large menonuclears, 22 per cent.; eosinophiles, 1 per cent. On August 5th she was etherized and Dr. W. L. Wallace removed the spleen. I append his notes. "Incision through the left rectus. Spleen found enlarged to the median line of the body, and extending parallel with.

to the median line of the body, and extending parallel with, and two inches below the lower border of the ribs. Liver, gallbladder, both kidneys, stomach, pancreas, and intra-abdominal fat normal in size and appearance. The spleen was slightly adherent and dark in color. The splenic veins were strikingly large and thin, as if their outlet was

"The light adhesions of the spleen to the diaphragm were broken up and the spleen easily delivered through the incision. The splenectomy was then accomplished by ligating the vessels separately with fine catgut; first, the splenic artery, in one very large upper and one large lower branch; then the splenic vein, in one very large upper and one large lower branch. The pedicle was then clamped close to the spleen and cut between the clamp and the ligatures, and the spleen was removed. On taking off the clamp the spleen rapidly contracted, pouring out a large amount of blood."

For several days following the operation she was exceedwith send and her recording to not looked for. Heart tonics in large doses were necessary to sustain the heart action. She complained of a great deal of pain in the left side. At the end of a week there was a marked improvement. She was now fairly comfortable. But owing to the discovery of a case of smallpox in the hospital she was second inoculation was successful and she reacted strongly. weak. She vomited frequently, retaining but little nourish-Added to this there was a troublesome diarrheea. She would have from three to eight liquid stools daily. This condition persisted until September 10th, when she again began to improve, and on October 2d she left the hospital.

The temperature following the operation reached 99.4° F. on August 6th. On the 9th it went up to 101° F. It then dropped to 99.4° F. On the 17th it was 100.2° F., on the 19th, 101.5° F. It then dropped to the normal and remained so for a week. On the 28th it went up to 101° F. From September 2d to the 6th the afternoon temperature was 102° F. It then gradually dropped to the normal.

Numerous blood examinations were made during this time. Immediately following the operation there was a slight increase in the number of red blood corpuscles and in the amount of hæmoglobin. The most striking change was the marked increase of leucocytes. Previous to the operation the leucopenia was pronounced, one count showing only 600 white cells. On August 6th, the day following the operation, the count showed 14,250 leucocytes. On the 7th there were 15,500, and on the 9th 19,500. This was the highest white cells count noted. From then on their number decreased. On August 24th the count showed but 10,000, and they have remained fairly constant since.

Leucocytosis is the rule following splenectomy. Sometimes the increase is pronounced. reports a case in which the white cells increased from 147,000 to 360,000. Six months later they numbered but 26,000.

The change in the distinctive count was also striking. Previous to the operation the distinctive count always showed a marked diminution in the number of polymorphonuclear neutrophiles, and a relative increase of the mononuclears, especially the large mononuclears. Following the operation, August 6th, the polynuclears suddenly increased to 78 per cent., the lymphocytes fell to 12 per cent., and the large mononuclears to 10 per cent. The polymorphonuclear neutrophiles remained about normal until September 17th, when a count showed: Polymorphonuclears, 46 per cent.; lymphocytes, 37 per cent.; large mononuclears, 16 per cent.; eosinophiles, 0.5 per cent.; mast cells, 0.5 per cent.

Blood count, September 24th: Hæmoglobin, 50 per cent.; red blood corpuscles, 3,700,000; white cells, 11,000; differential count, polymorphonuclear neutrophiles, 34 per cent.; lymphocytes, 44 per cent.; large mononuclears, 20 per cent.; eosinophiles, I per cent.; mast cells, I per cent. The blood now, with the exception of the number of leucocytes, closely approximates the blood picture previous to

the operation.

Sooner or later in almost all of the cases of splenectomy Sooner or later in almost all of the cases of splenectomy for splenic anæmia or Banti's disease a lymphocytosis has been noted. This had been looked upon as compensatory. In many cases the lymphatic glands became enlarged. The high percentage of large mononuclears in my case was rather unusual, but had also been noted in other cases. I have as yet found but very few eosinophiles. In the majority of the cases an increase has been noted. In one of the cases reported by Harris they numbered 14.4 per cent.

Pathological report: The spleen was sent to Professor H. S. Steensland. He reported: "The hardened spleen weighed 365 grammes. Microscopically it showed the usual changes found in chronic splenitis. There was nothing distinctive in the pathological changes—endothelial cells filling the pulp spaces, as observed by Gaucher, Harting and others were not accept."

cells filling the pulp spaces, as observed by Gaucher, Harris, and others, were not present."

Examination January 21, 1908, five and one half months after the operation: The patient showed a marked improvement in her condition. Her color was better. The brown spots had entirely disappeared. She weighed TI. pounds—a gain of forty pounds. Her appetite was good. She could eat anything without being distressed. Previously she had to be exceedingly careful. Menstruation was now regular. Before she was very irregular and always lost much blood. She was, however, still anæmic, and tired easily. There was also a great deal of tenderness and tired easily. There was also a great deal of tenderness along the bones of the forearms. The lymphatic glands were not enlarged, nor was the thyreoid. There had been no change in the gastric secretions. The hydrochloric acid and the ferments were still absent. The leucocytes were about normal. The hæmoglobin was also slightly increased.

The marked improvement in the general condi-

tion and in the blood picture following splenectomy in this case argues strongly in favor of the spleen being responsible for many of the symptoms. Just how the spleen influences the anæmia is still a question. Normally one of the functions of the spleen is to destroy the red blood corpuscles. In splenic anæmia it is believed that there is an increased de-Whether this is brought about by an enzyme or another agent is undetermined. The leucopenia must also be credited to the spleen. The marked leucocytosis following its removal cannot be explained in any other way. But we do not know whether the white cells are destroyed in the spleen, or whether the spleen secretes a toxine which destroys them in the circulation, or whether it secretes a toxine that has an inhibitory action on the white cell production in the bone marrow and lymphatic glands. The sudden change from leucopenia to leucocytosis would best be explained by the latter assumption. Splenectomy in itself is not a serious operation. In constitutional diseases like leuchæmia and cirrhosis of the liver, in which the enlarged spleen is only a part of a general condition, its removal cannot effect a cure. In splenic anæmia and Banti's disease, the spleen seems to be, in a measure at least, responsible for the production of the symp-Here its removal occasionally cures and usually benefits. Armstrong, in 1906, collected from the literature thirty-two cases of splenic anæmia and Banti's disease subjected to operation. There were twenty-three recoveries and nine deaths. Since then Carr has reported a successful case, but without any blood findings, and Torrance another.

I append a table of blood counts. In classifying the white cells under lymphocytes both the large and small lymphocytes are included. The large mononuclears include the transitionals. The latter cells were very large and the nucleus deeply indented. Occasionally a cell with large amphophile granulations was seen.

A letter received from the patient, dated May 14th, states that she is better in every way since I last saw her. Her appetite remains good, her color is better, the cedema and soreness have entirely disappeared.

Dr. L. A. Gould, of Schenectady, who has her under

observation, in a letter dated May 19, 1908, says: "I have observation, in a letter dated may 19, 1908, says. I have seen Miss M. several times during the past ten days. She looks much better than I have ever seen her before. I made a blood count a week ago and found: Hæmoglobin, 68 per cent.; red blood corpuscles, 3,900; white cells, 9,300. Differential count: Large mononuclears, 13,5 per cent.; no proposed parts of the proposed small mononuclears, 53.5 per cent.; polymorphonuclears, 31.5 per cent.; eosinophiles, 1.5 per cent."

717 EAST GENESEE STREET.

Our Beaders' Discussions.

A SERIES OF PRIZE ESSAYS.

Questions for discussion in this department are announced at frequent intervals. So far as they have been decided upon, the further questions are as follows:

LXXVIII.—How do you treat acute coryza? (Closed

LXXVIII.—How do you treat sick headache? (Answers due not later than October 15, 1908.)

LXXX.—How do you treat asphyxia neonatorum? (Answers due not later than November 16, 1908.)

swers due not later than November 10, 1908.) Whoever answers one of these questions in the manner most satisfactory to the editors and their advisers will receive a prize of \$25. No importance whatever will be attached to literary style, but the award will be based solely on the value of the substance of the answer. It is requested (but not required) that the answers be short; if practicable, no one answer to contain more than six hundred moveds. words.

All persons will be entitled to compete for the prize, whether subscribers or not. This prize will not be awarded to any one person more than once within one year. Every to day one person more than once within one year. Every answer must be accompanied by the writer's full name and address, both of which we must be at liberly to publish. All papers contributed become the property of the JOURNAL. OUR READERS ARE ASKED TO SUGGEST TOPICS FOR DISCUSSION. The prise of \$25 for the best essay submitted in answer to question LXXVII has been awarded to Dr. Maxwell S. Simpson, of Titusville, N. I., whose article appeared on the prise of \$25 for the prise of \$25 for the prise payable to the prise price of the prise price of the price o

PRIZE QUESTION LXXVII.

THE TREATMENT OF VARICOSE ULCER.

(Conc'uded from page 052.)

Dr. Austin Hogan, of Johnstoren, N. Y., says:

The proper and comprehensive treatment of varicose ulcer concerns itself not alone with measures and remedies directed to the cure of an ulcerated area, but (1) devises ways and means of combating and controlling the factors which enter into the causation of the condition; (2) takes into consideration the condition of the ulcer as regards (a) infection, (b) exuberant granulation and induration, (c) inflammatory reaction and bedema, (d) extent and involvement of underlying structures, as bones, joints, etc.; (3) endeavors to improve the blood supply by means of (a) rest, (b) elevation, (c) supportive measures, as intermittently applied elastic pressure, application of solidifying pastes to enveloping gauze bandages (Unna's method), compression, excision of venous trunks, and (d) cardiovascular medication; and (4) institutes prophylactic measures operating against a return of the ulcer as of prime importance in obtaining a permanent cure.

Important factors entering into the production of varicose ulcer are: (1) Hereditary influences; (2) age, sex (women past middle life); (3) local causes, injuries, femoral phlebitis, deficient innervation; (4) impediments to the venous flow, as constricting bands around the legs, faulty positions (crossing the legs), constipation, pelvic tumors, childbirth, and occupations requiring standing or straining.

Merest mention of some of these is all that is necessary to at once suggest simple and well known expedients for their correction and removal, while others (heredity, age, sex, childbirth, etc.) unchangeable in themselves are of value in directing the patient's mode of life so as to provide an efficient prophylaxis, and the local causes are subject to modifying influence if we exercise greater concern and care in this treatment, particularly in those afflicted with one or more predisposing factors.

It is not the purpose of the question, nor of this paper, to discuss the many well known ways advocated in the literature to meet the indications and subdue varicose ulcer, but the following conclusions have a bearing on any treatment promulgated: (1) The "pernicious activity" of frequent renewals is the most unfavorable criticism against the use of ointments, lotions, and pastes of various compositions. (2) In regard to operative measures, that while excision of venous trunks and nerve stretching are thought to do greater good than is attendant upon the rest enjoined by any operation; and (b) amputation is considered good surgery where there is extensive loss of substance associated with involvement of bone and ankylosis of the ankle joint, skin grafting is only necessary where there is very unusual loss of cutaneous and subcutaneous tissue. (3) That there is much merit in the imbrication of one inch adhesive straps over the ulcer, or the application of a rubber dam with superimposed compresses kept moist with boric acid solution, because they, in a measure, exemplify the principle underlying correct treatment.

The simplest treatment to meet indications and produce the desired result with least inconvenience to the patient is to be preferred, so in the morning before rising, when swelling and cedema are least, wash the leg with tincture of green soap, shave off the hair, rinse with sterile water, dry, and apply carbolic acid, full strength, to the ulcerated area; after it has turned white, neutralize with an excess of absolute alcohol, rinse again with sterile water,

apply a compress saturated with alcohol, and envelop the whole foot and leg in a sterile water com-

After twelve hours, curette any exuberant granulations, incise an indurated base or edge, taking care not to tap any varicosity, and apply wet compress moistened with nominal saline solution, boric acid solution, or corrosive mercuric chloride solution (1 in 5,000 or 10,000), or, if you prefer, cataplasm of kaolin; envelop all in oil of silk covering, keeping the patient in bed with the leg elevated.

After twelve to eighteen hours more have elapsed, remove all dressing, thoroughly dry with absorbent cotton or gauze sponges; apply thick coating of powdered calomel, and cover with a thin layer of absorbent cotton that has been shredded or teased to the consistency of finest cobweb; on top of this another thick coating of powdered calomel and again the thin layer of teased absorbent cotton; once more the calomel and again the cotton; and so on till we have five to ten layers of calomel immeshed in shredded absorbent cotton. Now place over all one or more liberal pads, one half to one inch thick, of absorbent cotton, and hold in place by a gauze bandage smoothly and snugly applied from the arch of the foot to the head of the tibia. This in turn is held firmly in place by a thin strip (one quarter inch wide) of adhesive plaster wound spirally from the foot, making several turns about the leg, not crossing the ulcer at any place, and attached above the bandage to the skin near the knee.

Every morning apply evenly and firmly, from foot to knee, a web elastic bandage, chosen because of the ability of a bandage to meet a reduction in volume and on account of its porosity, which allows transpiration and evaporation from the sound portions of the limb. This is to be removed on retiring each night.

After three days of enforced rest, with the leg elevated, if there has been no disturbance of the gauze bandage, etc., during the process of "taking" or "gluing," there is produced by the action of the serous exudation on the calomel and cotton meshes in conjunction with the intermittent elastic pressure of the 12 to 18 hour day bandage, an intimately adherent, relatively impervious dressing that promotes normal tissue tension and normal circulatory conditions as is evidenced by the cessation of all exudation and the abolition of any tendency to swelling and œdema, even under strain of the extremely liberal amount of standing or walking incident to ordinary occupations, so that the patient can pursue his vocation with no other attention to the leg than the simple adjustment of the web elastic day bandage.

After leaving in place for six weeks, remove the entire dressing, which, extremely adherent before, separates easily now, disclosing a somewhat moist, pearly or bluish white ephithelial surface, where previously existed the ulcer. Dry this well with absorbent cotton; expose to the air for several hours or more, and apply any drying powder; simple cornstarch answers every purpose; cover with thick cotton pad, over which place a piece of muslin somewhat larger, and hold all in place by two strips

of adhesive plaster, one passing above the level of the ulcer, the other below, and attached at the sides

to the skin of the leg.

Every morning apply the web elastic day bandage as before, to be removed on retiring each night, and six months or more of this simple after treatment will establish a sound cicatrix and wonderfully correct any tendency toward a reappearance of the lesion.

The administration thrice a day of strychnine (grain 1/30) in conjunction with Fowler's solution (m ii-v) or potassium iodide (grain ii-v) may be regarded as valuable auxiliary measure not to be overlooked.

Summary.

I. Take cognizance of the predisposing factors entering into its production, and institute prophylactic measures operating against its return as of prime importance in obtaining a permanent or true cure.

2. Avoid any treatment involving "pernicious activity," whereby the loss to repair is, obviously, greater than the gain.

greater than the gam.

3. Meet the indications as presented by the con-

dition of the ulcer.

4. The simplest treatment to meet these indications and produce the desired result with least inconvenience to the patient is to be preferred.

5. Intermittent, elastic pressure of twelve to eighteen hours' duration; to correct the arterial

ischæmia and venous hyperæmia.

6. Produce normal tissue tension and normal circulatory conditions by an adhering, protective, relatively impervious, slightly antiseptic dressing, preferably dry, supplemented by the intermittently applied elastic support to the venous flow.

7. Calomel immeshed in cotton—not cotton impregnated with calomel—subjected to the action of serous exudation and elastic pressure makes such a

dressing.

8. Calomel, shredded cotton, and web elastic day bandage, applied in the manner stated, will cure the

9. Corn starch, cotton pad, and web elastic day bandage, worn for six months or more, will keep it healed, and wonderfully correct any tendency toward a reappearance of it.

10. The administration of strychnine in conjunction with Fowler's solution or potassium iodide may be regarded as a valuable auxiliary measure not

to be overlooked.

Dr. Herman W. Coney, of Montreal, Can., writes:

General.—Insist on absolute rest in bed, with limb elevated to favor the return flow of blood. Give a liberal diet—plenty of good, plain food. Keep the bowels well opened. Iron and strychnine tonics if indicated. Calcium chloride in five grain doses, three times a day, for a few days appears to improve the condition of the blood and favor healing.

Local.—If there is much inflammatory reaction apply moist bichloride or boracic dressings for a few days till this subsides. The limb should then be thoroughly scrubbed with soap and water, shaved, and washed with some antiseptic lotion.

All dead skin and scabs should be cleaned away. If the base of the ulcer is indurated, or covered with unhealthy granulations, scarify with a sharp scalpel, or, better still perhaps, though this may require an anæsthetic, scrape thoroughly with the currette. An ointment composed of balsam of Peru, a drachm to the ounce of lanolin, should then be applied on pieces of lint cut to the exact size of the ulcer, covered with rubber tissue extending an inch or so beyond the edges of the lint, and the whole supported by a firm bandage reaching from the toes to the thigh. This dressing should be changed daily. Sometimes it seems well to vary the treatment, and for a day or so red wash may be used in the same manner, or aristol may be dusted on. In the case of very large ulcers skin grafting by Thiersch's method should be employed; the grafts being conveniently taken from a neighboring part of the leg, so the one dressing may do for both.

Prophylactic.—To prevent recurrence, or in some cases to aid in healing, an inch or so of the thickened and tortuous veins should be excised through small incisions at various points. Keep the patient in bed after this operation till healing is complete, to guard against embolism of vital organs; and rigid precautions must be taken against infection, as septic thrombosis might result. A French crèpe bandage should be worn by the patient after the ulcer heals, to support the circulation of the part. This bandage has the advantage that it may be taken off and cleansed as required, and it

affords firm, even pressure on the limb.

Dr. C. L. Sigler, of Pinckney, Mich., remarks:

The first essential in the treatment of varicose ulcers consists in the relief of the varicose veins causing the affliction. In mild cases a properly applied rubber or elastic woven bandage will so support the weakened veins that the ulcer will heal with little or no additional treatment. In more severe cases it may be necessary to institute more radical treatment, as the ligation or excision of the affected veins. At any rate, it is useless to try to heal the ulcer without first relieving the primary cause, and in many instances this may be done without putting the patient to bed, although rest will always facilitate the cure.

If the ulcer is recent, healthy, and has a tendency to heal little more is needed than to relieve the cause and perhaps apply some simple antiseptic powder, over which should be placed one or more thicknesses of sterile gauze. The bandage should then be put in place the first thing in the morning before the limb becomes at all swollen or congested, and should not be removed until the patient is

ready to retire at night.

If a pure rubber bandage is used the ulcer should be covered with the gauze, as otherwise the close contact with the secretions will aggravate the tendency to eczema, which almost invariably exists. The ulcer should be cleansed night and morning with warm water, to which has been added carbolic acid in the proportion of 1 to 40. If the ulcer is old and sluggish, the application of hydrogen peroxide will aid the cleansing and stimulate new granulations. Should the granulations be abundant

and watery the cleansing should be followed by the application of silver nitrate, or stick of copper sulphate. When the ulcer is deep, with a hard raised border, relief is often obtained by first paring or incising this border in several places, then drawing the edges in with several inch or half inch strips of adhesive plaster, care being taken that these are so placed that they will not interfere with the circulation.

If the healing does not take place in a satisfactory manner, skin grafts may be applied after the ulcer is in a healthy condition. These should be covered with a sterile dressing, moistened with a saline solution, over which is applied the usual bandage, and the patient kept in bed. In all cases the bandage should be begun at the toes and applied at least as far as the knee.

When the ulcer is quite or nearly healed a well fitting elastic stocking may be substituted for the bandage, but before this a bandage is to be preferred if the patient has ordinary skill in applying it.

Too much emphasis cannot be placed upon the fact that the prime factor in the cure of this class of ulcers is the relief of the varicose veins, and no benefit may be expected until these are relieved.

Dr. A. H. Powers, of Boston, observes:

A varicose ulcer can, like many another ill, be best treated before it appears. Where the veins of the leg are enlarged and tortuous, they should be so treated that the skin does not break and the ulcer commence. Occupation may need to be changed, for those who are continuously standing, like motormen, are the ones most subject to this trouble. Walking improves the circulation. Sitting and lying are the postures most favorable to normal veins.

Next to occupation and posture, I believe, that careful care of the skin is the best prophylactic. A leg carefully bathed every day has its circulation improved by the process, and in case by any accident the skin is broken there are fewer germs at hand to prevent the repair, especially if the leg is bathed with equal parts of alcohol and water. This bathing is very important. Lastly, some support of the leg is necessary. The most effective and satisfactory support is found in a well made and well fitting elastic stocking, but a light flannel bandage cut on the bias and carefully applied before getting out of bed will serve nearly as well, but is more troublesome, and on that account liable to be neg-

But if the bandage is of value before ulceration it is doubly so afterward. It then serves the double purpose of supporting the veins and holding the chosen dressing in position, and hence must extend from the toes to the knee or even higher if the veins are enlarged above that point.

If the ulcer is large and discharging profusely an elastic stocking is almost surely soiled and the dressing and discharges so damage the rubber that the elastic stocking has here a short period of usefulness, while a bandage may be washed and used many times. What the dressings shall be will depend on everal factors. The dressing must pro-

tect the tissues beneath and should be aseptic or antiseptic. If antiseptic it must be mildly so, for the cells of the ulcer are of so low a vitality that a strong antiseptic may be very injurious by killing the cells with which it comes in contact. The dressing should be capable of absorbing the discharges, else it may prove an injury by holding a septic discharge in contact with the ulcer. Plain sterile gauze, with a small amount of some sterile, oily substance just to prevent the sticking of the dressing when removed, is often the ideal one. A paste like the following will often serve a good purpose and especially on the skin about the ulcer:

B Salicylic acid, I to 3 per cent, Zinc oxide, Starch, ... ää 3iv; Petrolatum, ... 3j.

The starch in this paste renders it much more absorptive than the zinc oxide ointment, which is tried so frequently and often proves disappointing. The ulcer should be cleansed once or twice daily and not exposed to the air for a longer time than necessary, else a crust will form and irritate mechanically the tissues beneath.

Moist dressings may prove of much benefit for a time, but must not be continued for too long a time, as the ulcers will rarely heal completely under them, though marked improvement may be

If, in spite of careful support by bandage, painstaking cleansing of the ulcer, and a clean absorbing dressing, the ulcer does not improve, there remain other surgical means, only two of which I shall mention.

Curretting of the base of the ulcer, under an anæsthetic, especially if the leg is afterward elevated and the patient kept in bed, will cure or permit Nature to heal some of these ulcers; but if the ulcer is deep and has existed for considerable time skin grafting after Thiersch's method seems indicated, especially as the ulcer seems to be less liable to relapse. Along with this there may occasionally be the extirpation of some large tortuous veins of the leg and thigh with good results.

····· Correspondence.

LETTER FROM LONDON.

Doctors' Fees .- The African Sleeping Sickness .- Hot .1ir Treatment in the London Hospital.

LONDON, September 22, 1908.

The Daily Telegraph has lent its columns for the last few weeks to the discussion of the question of medical fees, and a large number of interesting letters have appeared from all classes of persons bearing on the question. The discussion was called forth by the report of an inquest held on the body of a man who cut his throat. The landlord of the house in which the man lived found him bleeding and hurried for a doctor, but was told by the medical man that he would not attend unless his fee of five shillings was first paid.

The landlord refused to be responsible for the payment, and the medical man did not go. The patient was removed by the police to the hospital, where he ultimately died. The coroner, Mr. Schröder, sensibly observed that "of course" medical men were not bound to attend without payment, and added that he had recently heard of a medical man who had attended twenty-three cases of supposed emergency without at first demanding his fee, with the result that he received payment only in two cases. In the particular case before the coroner the emergency did not appear to have been very great, for the man lived to be taken to a hospital and ultimately died there from delirium tremens. The remarks of the coroner on doctors and their fees brought forth a large number of letters. On the whole, these letters were favorable to medical men, and their rights in refusing to attend emergency cases unless their fee was paid were admitted. One of the writers drew a rather curious parallel between a medical man summoned to a case of attempted suicide and a miner summoned to assist at the rescue of comrades from a pit. The writer was unable to perceive that the miner went to the aid of his comrades because he was liable himself to be in similar straits at any time. On the whole, however, the correspondence bore striking testimony to the general benevolence and charity of the

members of our profession.

There is no doubt, however, that our charity and benevolence have been grossly abused by a large section of the public, and this state of affairs has been principally due to the medical men themselves. They have so accustomed the people to regard illness as an emergency in which the sufferers are morally entitled to aid from the first person at hand who is competent to render it that the question of remuneration has been suffered to remain in the background and only regarded as a secondary consideration. It must be admitted that it is an exceedingly difficult task for medical men to conduct their work upon absolutely business lines. There are no doubt circumstances in which the question of remuneration should not be considered, as in serious accidents involving many people and in which the first thing to be thought of would be the rescue of the sufferers or the treatment of the injuries they had sustained. At the same time there is doubtless truth in the observation that medical men as a body are not so businesslike in the keeping of accounts or in the exaction of payment as they might be. The Royal College of Physicians does not allow its members to sue for fees. Such a rule on the part of one of the most important of medical corporations lends countenance to the view that strict medical etiquette is incompatible with the demanding of fees. If such is the attitude of medical men themselves, it is no wonder that the public as a whole is disposed to regard the settlement of medical accounts as a matter which can be postponed to an indefinite period. It is only by the united action of medical men that this state of affairs can be remedied. An interesting example of the power of concerted action on the part of medical men is shown by the following incident which occurred recently. The Education Committee of Newcastle decided to advertise for a junior

medical officer at a salary of £200 a year. The British Medical Journal, however, refused to insert the advertisement at any price, on the ground that the salary offered was below the recognized rate of pay. The result was highly satisfactory, for not only did the committee readvertise the junior post at £250 a year, but they increased the existing officer's salary from £225 to £250 per annum. This gratifying result proves conclusively that concerted and firm action will suffice in many instances to bet-

ter the lot of the medical profession.

At the meeting of the British Association the subject of sleeping sickness was dealt with at a joint meeting of the Physiological and Zoological Sections. Mr. R. Newstead opened with a paper on the life history of tse-tse flies. The habitat of these flies was confined to certain definite belts of land, or fly tracts, which were mostly low lying, hot and humid. The flies did not travel very far from their habitat, perhaps about 300 yards, and never more than a mile. Dr. Nerenstein dealt with the action of atoxyl *in vivo* and *in vitro*, and confirmed Koch's and Ehrlich's experiments with regard to the resistance acquired by the trypanosomes to atoxyl. Dr. Moore dealt with the action of various drugs in trypanosomiasis, and stated that at the Liverpool School of Tropical Medicine they had obtained better results with mercury than with atoxyl. They also had obtained encouraging results by combinations of arsenic and antimony.

For some time negotiations have been in progress between the British and German governments as to an agreement to act together in combating sleeping sickness in their African possessions, and both governments have now agreed to the terms of a convention which will come into force on November 1st. The convention, which is for a period of three years, provides that British and German doctors and the officials in charge of the concentration camps shall keep in touch with one another to compare the results of their various researches. Segregation camps will be established on either side of the international boundary, while infected natives will be prevented from passing into uninfected districts, such persons being detained and segregated. The convention also provides for the notification to the officials of both governments of all infected areas and for taking effective measures for dealing with crocodiles or other animals which it may be found are the food of the fly which carries the disease.

The London Hospital is about to have a complete installation of hot air appliances similar to those in use at Carlsbad. This hospital is one of the best equipped in the country, and this installation will add yet another department of special treatment to the institution, which was the pioneer in the Finsen light treatment. The outfit is the gift of the Princess Hatzfeldt, and is being constructed at Wiesbaden. It is hoped that it will be ready for use in the London Hospital by October. Dr. Tvenauer, of Carlsbad, is the inventor of the apparatus, and he has promised to superintend its erection at the London Hospital. This treatment has been found very beneficial in painful rheumatic and gouty conditions, and particularly in old standing cases of rheumatoid arthritis and joint rheumatism.

Therapentical Aotes.

Treatment of an Acute Asthmatic Attack.— Mendel (Journal de médecine de Paris, September 5, 1908) remarks that the crisis may be checked by plunging the hands of the patient in very hot water, or the application of a mustard footbath. The fumes from a teaspoonful of the following powder ignited on a plate should be inhaled:

| 0 | | | |
|------------------|--------------------------|--|----|
| \mathbf{P}_{i} | | nitrate, | s; |
| M. | Pulverized Pulverized | stramonium leaves, belladonna leaves, | v. |

Pron's asthma remedy, a powder to be ignited and the fumes inhaled, differs from the foregoing. It reads as follows:

| 70 | D 1 1 1 | 1 11 1 | - 1 | | | | | | | | | | |
|-----|------------|-----------|-------|------|------|-----|----|---|-----|-----|-------|------|---|
| B | Pulverized | belladoni | 1a 16 | eav | es, | | | | | | | | |
| | Pulverized | stramoni | um | lea | ves, | | | | | | āā 3 | 1155 | ; |
| | Potassium | nitrate, | | | | | | | | | | 3ss | ÷ |
| | Pulverized | opium, | | | | | | | | | gr. | XV | |
| 3.5 | C Ome ton | coconful | to 1 | 00 1 | anii | had | in | 0 | 001 | 100 | r and | the | ρ |

fumes inhaled.

If the bronchial secretion is very profuse the fol-

| | ng pills | | | | | | | | | | | | |

| 3.5 | -t for mi | n | Jo sere | | | | | | | | | | |

Sig.: One pill three or four times daily.

When the attack is very severe recourse is had to pyridine, a colorless and very volatile fluid of a strongly nauseating odor. About ten drops are thrown on a handkerchief and the vapor inhaled, or better a teaspoonful of the fluid is poured into an open saucer placed in the middle of the room occupied by the patient.

Vaginal Injection in Uterine Cancer.—The following formula is credited to Delettrez in Bulletin général de thérapeutique for September 23, 1908:

| | Boiling water,Oii; | |
|----|---|--|
| | Oil of turpentine, | |
| | Calcined magnesia, | |
| M. | Allow to cool to about 86° F. before using. | |

[The oil of turpentine should be intimately incorporated with the magnesia before adding the boiling water.]

To relieve the pain of uterine cancer it is recommended by Lutaud (Bulletin général de thérapeutique, August 23, 1908) to administer the following mixture:

| B | Tincture | of thuja,3i | , |
|-------|-----------|---|---|
| | | of potassium arsenite, | |
| | | acacia, | |
| | | water, | |
| M. | et. Sig.: | One teaspoonful three times a day befor | e |
| monle | | | |

The Hypodermic Administration of Potassium Bromide.—It is frequently desired to administer potassium bromide hypodermically, owing to the inability of the patient to take a solution of the salt by the mouth, on account of its taste or by reason of its disturbing effect on the stomach. The objections to injecting solutions of the salt beneath the skin lay, heretofore, in the irritation set up by strong solutions and the comparative uselessness of weak edutions. Rebizzi, of Florence (La Semaine

médicale, September 23, 1908), has devised a formula which provides a solution that may be used hypodermically without any ill effect and which at the same time is strong enough to provide an ordinary dose of the salt (15 grains). The formula follows:

| 0440 | | | | | | | | | | | | | | | | |
|--|-----------|---|--|------|------|--|--|--|--|--|--------|----|---|-----|------|-----|
| $\mathbf{P}_{\!\scriptscriptstyle{k}}$ | Potassiu | | | | | | | | | | | | | | | |

| | Distilled | | | | | | | | | | q. | S. | 1 | a c | l 3i | 11. |
| 7.4 | ft soluti | 0 | | | | | | | | | | | | | | |

Thirty minims of a solution prepared after the foregoing formula will contain fifteen grains of potassium bromide, and this amount is directed to be injected into the front part of the thigh. If it is desired to administer thirty grains at one dose an injection of thirty minims is made in each thigh, the needle being made to penetrate rather deeply. The proportion of bromide should be slightly reduced in the winter, as the cold weather may cause precipitation of some of the salt. This, however, can be overcome by heating the container.

In this solution the carbolic acid acts as a local anæsthetic and keeps it sterile, but its principal advantage lies in the prevention of the diapedesis which is generally observed to follow injections of potassium bromide. As for the sodium sulphate, its function is to facilitate absorption and favor the elimination of the carbolic acid. Rebizzi has never noticed any sharp pain follow the injection; in rare cases a slight local cedema has been produced, which is easily removed by the application of ichthyol ointment.

The Symptomatic Treatment of Cancer of the Stomach.—Rummo (Studium, March, 1908; Revue de thérapeutique, September 15, 1908) prescribes the following mixture as a stomachic tonic and digestive medicine for patients afflicted with cancer of the stomach:

| B | Fluid extract of cinchona, Fluid extract of kola, Fluid extract of coca, Fluid extract of condurango. | .āā 3iii |
|----|--|---------------------|
| | Tincture of nux vomica, | .āā 3iv |
| VI | Oleosaccharure of peppermint, { Oleosaccharure of vanilla, Syrup of orange peel,enough to m | .āā ǯiii nake Oi |

To the syrup of orange peel add the mixture of other ingredients; allow to macerate for twenty-four hours and filter. Dose: One liqueur glassful before the two principal meals.

To Control Vomiting in Consumptives.—Marfan, (cited in *Journal de médecine de Paris* for September 26, 1908), gives four to five drops of the following solution in a little water:

| 11 | Alcohol, | 1 |
|----|---|---|
| | Tincture of iodine, Carbolic acid, crystals, |) |
| M. | | |

For Gastroenteritis.—The following is recommended to be given in cachets twice daily with meals:

| P_i | | | |
|-------|-----------|------------|------------|
| М | Magnesium | hydroxide, | gr. viiss. |

NEW YORK MEDICAL JOURNAL

INCORPORATING THE

Philadelphia Medical Journal and The Medical News.

A Weekly Review of Medicine.

Edited by

FRANK P. FOSTER, M. D., and SMITH ELY JELLIFFE, M. D.

Address all business communications to

A. R. ELLIOTT PUBLISHING COMPANY,
Publishers.

66 West Broadway, New York.

PHILADELPHIA OFFICE: 3713 Walnut Street. CHICAGO OFFICE: 160 Washington Street.

SUBSCRIPTION PRICE :

Under Domestic Postage Rates, \$5; under Foreign Postage Rate, \$7; single copies, fifteen cents.

Remittances should be made by New York Exchange or post office or express money order payable to the A. R. Elliott Publishing Co., or by registered mail, as the publishers are not responsible for money sent by unregistered mail.

Entered at the Post Office at New York and admitted for transportation through the mail as second class matter.

NEW YORK, SATURDAY, OCTOBER 10, 1908

HUMAN AND BOVINE TUBERCULOUS DISEASE.

There are few if any physicians, we are convinced, who believe everything they see in the newspapers, but the general public, knowing nothing of the facts, is prone to accept press statements as to medical matters as correct. This credulity on the part of the community is particularly to be deplored in its relation to reports of the proceedings of the recent International Congress on Tuberculosis which, so far as papers and discussions were concerned, closed last week, because one of the chief functions of the congress was that of diffusing knowledge among the people, and without such knowledge the campaign against tuberculous disease would have to be carried on with little or no help from the public.

In the matter of the Washington congress, the newspaper reporter seems to have given free play to his imagination, and the papers have been almost unanimous in circulating false reports. They went so far as to put a striking statement into the mouth of an eminent physician who was not even present on the occasion when he was said to have proclaimed it. They have sedulously given their readers to understand that a rancorous controversy took place as to the reality of human tuberculous disease of bovine origin, and have pictured almost all the other participants in the congress as manifesting violent opposition to Koch's well known views on the subject. The actual proceedings did not justify such a picture. Koch was greeted with general enthusiasm and with the deference due to such a distinguished man of science. Those who dissented from some of his views on the relations between human and bovine tuberculous disease expressed themselves courteously and with no more warmth than the vast importance of the subject called for.

Koch does not seem to have receded essentially from the position which he took in London six years ago. He does not deny that the human and the bovine tubercle bacilli are of one species, though he still insists that they show certain recognizable differences. To array the view of those who do not agree to all that Koch infers as "the American view," as some of the newspapers have done, is grotesque, for Koch himself avows that it was the work of an American investigator, Theobald Smith, that led him to undertake his own researches concerning the differences between the one bacillus and the other, and the dissent from some of Koch's inferences has come quite as much from men of other nationalities as from Americans.

As we understand it, Koch admits the transmissibility of bovine tuberculous disease to the human subject, but insists that it has not yet been demonstrated that pulmonary manifestations of the disease occur when it is thus transmitted. Even on this point, however, Koch urges that further investigation be carried on, and he specifies the conditions which, in his opinion, ought to be observed in subsequent researches. Perhaps he is too rigid in his requirements and too sweeping in his deductions-and we think he is-but we cannot agree that the tenacity with which he clings to his fundamental proposition can justly be called obstinacy, as we have heard it termed. He has a right to demand that his position shall be refuted beyond a doubt before it is held to be utterly discredited. In the meantime, of course, the world must conduct the struggle against tuberculous disease on the assumption that he is mistaken; we must neglect no means to restrict the possibility of human infection from bovine sources.

THE ARMY CANTEEN.

At the sixteenth annual meeting of the Association of Military Surgeons of the United States Dr. Anita Newcomb McGee, formerly an acting assistant surgeon in the army, read a paper entitled Facts About the Army Canteen. The paper appears in the October number of the Military Surgeon. Dr. McGee tells us at the outset that her object in gathering the data which form the basis of her paper was to justify her in taking an active interest in the restoration of the canteen, but she has found that she is not warranted in taking such an interest. The chief feature of her conclusions, as it seems to us, is the inference that there has been such a slight difference between the amount of alcoholism re-

ported during the canteen years (1889 to 1898) and that reported since the abolition of the canteen as to show, in conjunction with other facts, that "the presence or absence of the canteen has a decidedly minor effect on drunkenness in comparison with other influences." Again, in closing the discussion, she declared that the official facts published by the War Department showed that the canteen was of insignificant importance in comparison with other causes affecting drunkenness and disease in the army. She is quite sure that, on the whole, the abolition of the canteen has not resulted in increasing the number of saloons in the vicinity of military posts.

The published discussion of the subject of Dr. McGee's paper shows a decided diversity of opinion among those who took part in it. Colonel Valery Havard expressed a sentiment which seems to us of far greater importance than the question of whether or not the abolition of the canteen has resulted in an increase of drunkenness among our soldiers. "My objection," he said, "to the present policy of excluding wine and beer from the canteen is that it renders the life of the soldier less pleasant, more irksome; it violates his personal liberty, that is, those rights to which all men are reasonably entitled. In regard to his eating and drinking, he ought to enjoy the usual privileges of any citizen, so long as he is not guilty of any excess which, in the opinion of his superiors, might be detrimental to his health or morals." Colonel Joseph K. Weaver, of the National Guard of Pennsylvania, presented data tending to show that beer drinking regiments were not so efficient as those that eschewed beer. Major Charles E. Woodruff pointed out that the sick reports did not show the amount of drunkenness. "We get very few cases in the hospitals," he said, "though since the abolition of the canteen they are more numerous and more violent," He added that the saloons around the post, which had not flourished during the days of the canteen, were "rich now if not more numerous." Major Woodruff thinks that the men enlisted during the last few years are of a class superior to those of twenty years ago, when, according to his observation, many old soldiers "got drunk as regularly as pay day came, and stayed drunk until their money was gone." He closed with this positive statement: "I know that the abolition of the canteen has increased drunkenness, and the drinking is done outside." Medical Director John C. Wise, of the navy, thought that the facts collected by Dr. McGee were convincing, and that the influence of the canteen in the Pennsylvania National Guard was not conducive to discipline or efficiency, also that the drinkers of wine and beer were "more susceptible to the unit rays and to digo tive di turbances.

HISTOPLASMOSIS

With the territorial expansion of the United States, opportunities for new research have been abundantly presented, although it is well recognized that our native veins have not yet ceased to yield important new "finds." Workers in the Philippines have brought together rich collections of rare and exotic diseases, and within very recent times the Panama Zone promises to show novelties of enduring interest. In the most recent issue of the Archives of Internal Medicine for September 15th, Dr. Samuel T. Darling, chief of the Board of Health Laboratory, Ancon, Canal Zone, Panama, describes a new parasitic protozoon Histoplasma capsulatum, which he has encountered three times during the past two years and a half in the Ancon Hospital.

The clinical phenomena induced by this parasite, as well as the tissue changes brought about, are suggestive of the Indian disease kala-azar, which has as a cause an interesting parasite, the Leishman-Donovan body, termed variously Leischmania Donovani and Piroplasma Donovani. This parasite (Histoplasma) is new and is the first recorded instance in the New World of a parasite of this type. It is to be regarded as a flagellated protozoon, and, so far as can be stated, it is an inhabitant of surface pellicles of tropical waters, probably derived from the intestinal tracts of insects.

Clinically, the disease is characterized by splenomegaly, emaciation, remittent temperature, and leucopenia. The individuals affected were two Martinique negroes and one Chinaman, all resident in the district for many years. In one a terminal bronchopneumonia brought about the fatal issue; in the others there were pseudogranulomata in the lungs. Thus in many respects the disease resembles kalaazar, though the pseudogranulomata of the lungs are not characteristic of the latter disease, and the parasite presents minute histological variations from the Piroplasma Donovani. The disease may be met with, Darling thinks, in unhygienic and insalubrious regions of tropical America, and sanitarians and tropical workers should be on the lookout for it.

THE BLOOD IN DIPHTHERIA.

It is generally held that myelocytes are more numerous in the peripheral blood in cases of diphtheria than in other infective diseases, and it has been stated that when the percentage of these cells reaches two or more a serious prognosis is warranted. Many authors, however, have dissented from these generally accepted statements about the hæmatology of diphtheria, which may be traced to a paper by Engel, which was published in 1897. In

a recent study of The Leucocytes in Diphtheria Before and After the Administration of Antitoxine. by Dr. Howard T. Karsner (University of Pennsylvania Medical Bulletin, September), no constant myelocytosis was discovered. The author concludes from an examination of thirteen cases of diphtheria, in which thirty-seven cell counts and differential leucocyte counts were made, that diphtheria is usually accompanied by a moderate leucocytosis. In extremely toxic cases and extremely mild cases this leucocytosis may be absent. The differential counts show nothing abnormal in the proportions of the various kinds of white corpuscles. Neither the degree of leucocytosis nor the proportion of the various types of cells indicates, except within very broad general lines, the severity of the infection or the probable outcome of the disease. The administration of antitoxine has no appreciable effect on the degree of the leucocytosis, on the proportion of the various forms of cells, or on the staining reactions of the celis.

CLINICAL OBSERVATION A LA SHERLOCK HOLMES.

In La Clinique for September 11th M. Léon Mac-Auliffe gives an entertaining sketch of the methods employed under the direction of M. A. Bertillon in the anthropometric measures for the identification of the criminals and vagabonds of Paris. It is not uncommon, he says, for a hundred arrested persons to be examined in the course of a forenoon. They are weighed and measured and photographed, as we all know, but the descriptive memoranda dictated by trained employees, or special agents, are of great importance in the data depended upon for subsequent recognition.

These special agents know nothing of medicine or of scientific anthropometry, but long experience has given them a wonderful ability in observing and describing such personal peculiarities as may serve the purpose of identification, so that they are veritable Sherlock Holmeses. With admirable precision they cry out the complexion, the general configuration of the face, the shape of its constituent features, the smallest scars, the appearance and size of birth marks, the signs of old bony injuries, etc. It is all done in the course of a few minutes, and M. Mac-Auliffe declares that it could not be better done by the most expert of clinical professors. He adds that no anatomist has ever exceeded the precision with which, in a few seconds, there are described the details of a person's ear, for example, the outlines of the helix, the antiragus, the lobule, and the folds of the anthelix. Thousands and thousands of such data have thus been recorded, says the author, but

there is as yet no distinctive criminal morphology, whatever Lombroso may have said to the contrary.

M. Mac-Auliffe argues that the acuteness and accuracy of observation displayed by these special agents might with great advantage be imparted to students of medicine and employed by them in detecting and recording the peculiar appearances presented by the sick. There can be no doubt, we think, that the lesson drawn by M. Mac-Auliffe is one that deserves to be impressed upon students and practitioners of medicine. The physicians of a generation or two ago were unquestionably more minute observers than we are to-day. We have learned to lean upon instruments of precision, almost to the exclusion of our ordinary powers of observation. Our regard for the results of the employment of such instruments is amply warranted, but it is foolish to disregard what we can see and hear and feel without them, for they are not always at our command. In no way can the young physician better train himself to become an expert diagnostician than by cultivating that attention to minutiæ which is the main characteristic of Sir Conan Doyle's famous detective. The deductive faculty will almost grow of itself.

THE ETHICS OF QUARANTINE.

It is stated in the Rassegna sanitaria di Roma for September 1st that Commendatore Santoliquido, director of the Italian Health Board, in the course of a recent interview granted by him to a representative of the Tribuna regarding the precautions taken to prevent an outbreak of cholera in Italy, digressed to relate the following incident:

Some time ago (no date mentioned) a steamer arrived at Naples with a party of American tourists on board. During the passage some deaths from smallpox had taken place. In order to avoid the discomforts of a prolonged quarantine for the rich passengers, the bodies were buried at sea and no report was made to the authorities when the ship docked. After disembarking at Naples, some of the party went to Rome and others to Florence, and the ship had orders to pick them up at Liverpool. In Rome some of the party fell ill with smallpox, and the sanitary authorities, on hearing of this, had them isolated immediately. As a precautionary measure, the authorities in Florence were put in possession of the facts, and without any fuss every person who had possibly come in contact with any of the party was vaccinated, including the hotel employees, the waiters of all the cafés in Rome, the street car conductors, and others. The disease disappeared and nobody was any the wiser. The ship was traced to Liverpool and the captain punished. "But," said the director, "he should have received a reward, because he showed to the whole of Europe how a disease might enter into Italy, but be isolated."

Evidently this particular commendatore is of a liberal and daring turn of mind; probably he would run a battleship through submarine mines without hesitation.

Rems Items.

Changes of Address.—Dr. W. C. Hollopeter, to 1411 Spruce Street, Philadelphia; Dr. C. A. Van Dervoort, to 1118 Pennsylvania Building, Philadelphia; Dr. Harris Weinstein, to 825 Lexington Avenue, New York; Dr. Edmund Russell, from Houtzdale, Pa., to Waterbury, Conn.

The Syracuse, N. Y., Academy of Medicine held a meeting on Tuesday evening, October 6th. Dr. Samuel Lloyd, of New York, read a paper entitled The Surgical Treatment of Post Pneumonic Abscesses of the Lung. Dr. Henry L. Elsner and Dr. G. M. Price opened the discussion.

Public Lecture at the New York Academy of Medicine.—Dr. Charles A. L. Reed, of Cincinnati, will deliver a public lecture at the New York Academy of Medicine on the evening of Thursday, October 29th. The subject will be The Character, Status, and Economic Value of a National Department of Public Health tional Department of Public Health.

The College of Physicians of Philadelphia.-At the stated meeting of the College of Physicians of Phila-delphia, held on Wednesday, October 7th, only the private business of the college was transacted. The librarian announced the addition of one hundred and fifty volumes to the library during the summer.

Alumni Association of Mount Sinai Hospital, Philadelphia.—At a recent meeting of the Resident and Ex-resident Alumni Association of the Mount Sinai Hospital, Philadelphia, the following officers were elected: Dr. Julius L. Werner, chairman; Dr. Benjamin H. Mauer, vice chairman; Dr. Michael Austin, secretary and treasurer; Dr. Jacob Levy, historian.

Contagious Diseases in Chicago.—During the week ending September 25, 1908, there were reported to the Department of Health 353 cases of contagious diseases, as follows: Diphtheria, 106 cases; scarlet fever, 74 cases; measles, 16 cases; chickenpox, 10 cases; typhoid fever, 70 cases; whooping cough, 18 cases; tuberculosis, 41 cases; diseases of minor importance, 8 cases.

American Chemical Society.—The New York Section of the American Chemical Society held the first regular meeting of the session on Friday evening, October 9th, at the Chemists' Club. Mr. Hudson Maxim delivered an address on the Warfare of the Future, in which he referred to the use of high explosives and torpedoes in wars, and exhibited some interesting explosive material.

Medical Society of the County of Ontario, N. Y.— The annual meeting of this society will be held in Canandaigua on Tuesday, October 13th, at 10:30 a. m. Dr. C. P. W. Merritt, of Clifton Springs, will deliver the annual address of the president. Dr. H. I. Davenport, of Canandaigua, will read a paper on Tests for Albumen. Dr. F. C. Busch, of Buffalo, will read a paper on Enzymes and Hor-The annual banquet will be served at the close of the meeting.

American Pharmaceutical Association.-The Philadelphia branch of this association announces that among the subjects which will be discussed at forthcoming meetings the subjects which will be discussed at forthcoming meetings of the association are the following: November 3d, Compounding and Dispensing, and the Sale of Liquors in Drug Stores; December 1st, The Use and Value of Pure Food and Drug Laws; February 16, 1909, The Transformation of Elements and the Modern Theories of Matter; April 6, 1909, The Drug Laboratory of the Bureau of Chemistry.

The Wesley M. Carpenter Lecture was delivered at the New York Academy of Medicine on the evening of Thursday October 3th by Dr. German Sims Woodhead

Thursday, October 3th, by Dr. German Sims Woodhead, professor of pathology in the University of Cambridge. The subject was Some Phases of the Evolution of Modern Preventive Medicine as Illustrated by the Present Cam-Preventive Medicine as Illustrated by the Present Campaign against Tuberculosis. It was originally announced that Dr. Andres Martinez-Vargas, of Barcelona, Spain, would deliver this lecture, but he was unable to be present.

The Obstetrical Society of Philadelphia.—A stated meeting of the society was held on Thursday evening, October 1977. The programme method of the following

by Dr. C. C. Norris: Buried Catgut, and a Subcuticular Stitch in Plastic Operations on the Perinaum, by Dr. Brooke M. Anspach: The Indications for Casarean Section as Determined by Antepartum Cephalometry, with a Brief Report of an Unusual Case with Positive Indications, by Dr. J. C. Applegate.

The Kentucky State Medical Association.-At the The Kentucky State Medical Association.—At the fifty-third annual meeting of this association, which was held in Winchester, Ky., recently, officers for the ensuing year were elected as follows: President, Dr. I. A. Shirley, of Winchester; first vice president, Dr. M. F. Coomes, of Louisville; second vice president, Dr. B. F. Parrish, of Midway; third vice president, Dr. J. C. Karrick, of Lexington; secretary, Dr. A. T. McCormack, of Bowling Green; treasurer, Dr. W. B. McClure, of Lexington. Louisville was chosen as the next place of meeting.

The Northwestern Medical Society.—A stated meet-

The Northwestern Medical Society.—A stated meeting of this society was held in Philadelphia on Monday evening, October 5th. The programme consistent of a "symposium" on diseases of the biliary passages, and papers on the subject were read as follows: Bacteriology of the Biliary Passages, with Special Reference to Typhoid Carriers, by Dr. R. C. Rosenberger; The Medical Aspect of Disease of the Biliary Passages, by Dr. J. C. Wilson; The Therapeutics of Diseases of the Biliary Passages, by Dr. E. Q. Thornton; The Surgery of the Biliary Passages, by Dr. J. Chalmers Da Costa.

The Campaign Against Tuberculosis in the United States is the title of a book of nearly five hundred pages recently published by the New York Charities Organization Prevention of Tuberculosis at the expense of the Russell Sage Foundation. The book contains a directory of institutions in which sufferers from tuberculosis are treated, and of organizations interested in the study, treatment, and prevention of the disease. The history of the growth of the movement for the prevention of tuberculosis is given, and abstracts from the legislation relating to this disease in force in the various States are included.

force in the various States are included.

The Health of Minneapolis.—During the month of August, 1908, there were reported to the Department of Health of the City of Minneapolis the following cases of transmissible diseases: Diphtheria, 72 cases, 8 deaths; scarlet fever, 10 cases, 0 deaths; smallpox, 3 cases, 0 deaths; typhoid fever, 8 cases, 3 deaths: tuberculosis, 33 cases, 24 deaths. The total number of deaths from all causes was 270, in an estimated population of 300,000, corresponding to an annual death rate of 9.60 in 1,000 of population. Of the total number of deaths 60 were of children under five years of age, and of these 35 were due to diarrhoal diseases. There were 18 still births.

Scientific Society Meetings in Philadelphia for the Week Ending October 171, 1908:

Monday, October 12th.—Section in General Medicine, College of Physicians; Wills Hospital Ophthalmic Society.

Tussday, October 13th.—Philadelphia Pediatric Society;

Bothand Section Academy of Natural Sciences

Botanical Section, Academy of Natural Sciences.
Wednesday, October 14th.—Philadelphia County Medical

THURSDAY, October 15th.—Section in Gynæcology, College of Physicians; Section Meeting, Franklin Institute; Medical Society of the Woman's Hospital; Section in Ophthalmology, College of Physicians.

FRIDAY, October 16th.—American Philosophical Society.

Frinay, October 16th.—American Philosophical Society.

The Windham County, Conn., Medical Association.—
The semiannual meeting of this association will be held at the Hooker House, Willmantic, Conn., on Wednesday, October 14th. The programme includes the following papers, in addition to the presidential address: Acute Specific Urethritis, by Dr. W. H. Judson, of Danielson; The Benefits of Saline Cathartics, by Dr. C. E. Simonds, of Willimantic; Psychotherapeutics, by Dr. Rienzi Robinson, of Danielson; The Diagnosis and Treatment of Certain Fractures, by Dr. Homer Gage, of Worcester, Mass. The officers of the association are: Dr. Robert C. Paine, of Thomson, president; Dr. John Weldon, of Willimantic. vice president; Dr. James L. Gardner, of Central Village, secretary.

The Buffalo Academy of Medicine.- The first regular meeting of the Section in Pathology was held on Tuesday evening, October 6th. Dr. Nathan Raw, of Liverpool, England, one of the delegates to the International Congress on Tuberculosis, read a paper on the Relation between Human and Bovine Tuberculosis

A stated meeting of the academy will be held under the auspices of the Section in Medicine on Tuesday evening, October 13th. Dr. Julius Ullman will present a report of the Committee on Contagious Diseases and Municipal Contagious Hospital. Dr. Robert J. Wilson, of New York, will read a paper on Contagious Disease Hospitals: Their Medical Contagious Disease Rospitals: Their Rospitals: Their Rospitals: Their Rospitals: Their Rospitals: Their Rospitals: Their Rospitals: T

New York and New England Association of Railway Surgeons.—The eighteenth annual meeting of this as-sociation will be held at the New York Academy of Medicine on November 17th and 18th, under the presidency of Dr. F. A. Stillings, of Concord, N. H. The first session will be devoted to a "symposium" on the following topic: What are the Causes Leading to Railway Accidents, and what Remedies can be Suggested? Eight papers will be read, and the general discussion will be participated in by a number of men who have given the subject careful consideration. Railway officials and members of the medica! profession are invited to attend the meeting. Dr. George Chaffee, 338 Forty-seventh Street, Brooklyn, is the secretary of the society.

Vital Statistics of New York.—During the week end-

ing September 26, 1908, there were reported to the Department of Health of the City of New York 1,271 deaths from all causes, of which 666 were in Manhattan, 103 in the Bronx, 402 in Brooklyn, 70 in Queens, and 30 in Richmond. The death rate for the week, in an estimated population of 4.442,685, was 14.09 in 1,000 of population, as against a death rate of 16.62 in the corresponding period in 1907. The death rates in the five boroughs for the week were as follows: Manhattan, 15.15; the Bronx, 16.40; Brooklyn, 14.05; Queens, 15.70; Richmond, 20.41. Of the total number of deaths 471 were of children under five years of age, and of these 193 were due to diarrhœal diseases. There were 136 still births. Seven hundred and forty-eight marriages and 2,302 births were reported during the week.

Infectious Diseases in New York:

We are indebted to the Bureau of Records of the De-partment of Health for the following statement of new cases and deaths reported for the two weeks ending October 3, 1908

| | Sept. 26 | | Oct. 3 | |
|--------------------------|----------|---------|--------|--------|
| | Cases. | Deaths. | Cases. | Deaths |
| Tuberculosis pulmonalis | 530 | 172 | 481 | 153 |
| Diplitheria | 255 | 24 | 266 | 21 |
| Measles | 54 | | 96 | 2 |
| Scarlet fever | 143 | 7 | 102 | 4 |
| Smallpox | | I | | |
| Varicella | 17 | | | |
| Typhoid fever | 127 | 29 | 100 | 1.0 |
| Whooping cough | 25 | b | 21 | 2 |
| Cerebrospinal meningitis | 8 | 8 | 7 | 5 |
| | | | | |
| Totals | 1,159 | 247 | 1,073 | 200 |

The Mortality of Chicago.-During the week ending September 26, 1908, there were reported to the Department of Health of the City of Chicago 583 deaths from all causes, as compared with 525 for the previous week and 549 for the corresponding period in 1907. The annual death rate, in an estimated population of 2,166,055, was 14,04 in 1,000 of population. Of the total number of deaths 217 were of children under five years of age, and of these 166 were less than one year of age. The principal causes of death were: Apoplexy, 11 deaths; Bright's disease, 42 death were: Apoptexy, 11 deaths; Digits disease, deaths; bronchitis, 9 deaths; consumption, 49 deaths; cancer, 21 deaths; diphtheria. 0 deaths; heart diseases, 43 deaths; intestinal diseases, acute, 142 deaths; measles, 2 deaths; nervous diseases, 15 deaths; pneumonia, 35 deaths; scarlet fever, 7 deaths; suicide, 11 deaths; typhoid fever, 18

deaths; violence (other than suicide), 35 deaths; whooping cough, 2 deaths; all other causes, 132 deaths.

Medical Society of Virginia.—The thirty-ninth annual meeting of this society will be held in Richmond on Tuesday, Wednesday. Thursday, and Friday, October 20 to 23, 1908. The headquarters of the society will be at The 1908. The headquarters of the society will be Jefferson, where all meetings will be held. The first ses-Jefterson, where all meetings will be held. Ine first session will be held on Tuesday evening. The Hon. D. C. Richardson, Mayor of Richmond, will deliver the address of welcome, after which Dr. William Francis Drewry, of Petersburg, will deliver the annual presidential address. A splendid programme has been prepared, consisting of fifty-eight papers on subjects of interest to the general hifty-eight papers on subjects of interest to the general practitioner, including a symposium on anæsthetics. Clinics will be held daily, from 8:30 a. m. to 9:30 a. m., at the Memorial and Virginia Hospitals, and on Thursday evening the members of the society will attend a joint conference of the State, city, and county boards of health. The officers of the society are as follows: President, Dr. William Francis Drewry, of Petersburg; vice presidents, Dr. Floyd J. Gregory, of Keysville, Dr. J. B. Fisher, of Midlothian, and Dr. H. R. Dupuy, of Norfolk; secretary, Dr. Landon, B. Edwards of Richmond: corresponding secre-Landon B. Edwards, of Richmond; corresponding secretary, Dr. John F. Winn, of Richmond; treasurer, Dr. R. M. Slaughter, of the Theological Seminary.

Personal.—Dr. Harvey W. Wiley, Chief of the Bureau of Chemistry of the United States Department of Agriculture, has been elected an honorary member of the Physico-chemical Academy of Italy, and has been awarded a medal of the first class by the same academy.

Dr. Paul G. Woolley, who has been director of the Government Serum Laboratory in Phrapatoom, Siam, for the past five years, has accepted the position of associate professor of clinical pathology in the University of Nebraska

College of Medicine.

One of Medicine.

Dr. Willis P. Jones has been elected attending surgeon to the Grady Hospital, Atlanta, Ga., to succeed Dr. William Perrin Nicholson, who resigned recently.

Dr. Anne H. Thomas, of Philadelphia, has been appointed assistant physician to Bryn Mawr College.

Medical Day in Founders' Week.—The physicians of Philadelphia celebrated the two hundred and twenty-fifth anniversary of the founding of their city on Thursday, Oc-At 10 a. m. a meeting was held in the Walnut Street Theatre, which was largely attended by members of the medical profession and other scientific bodies, and the public. Dr. George A. Piersol, of the University of Pennpublic. Dr. George A. Piersol, of the University of Pennsylvania, delivered an address on The Medical Colleges and Allied Institutions of Philadelphia. Dr. Solomon Solis-Cohen, of Jefferson Medical College, delivered an address on Some of the Great Medical Teachers of Philadelphia; and Dr. James M. Anders, of the Medicochirurgical College, concluded the formal addresses by speaking on The Development of Practical Medicine in Philadelphia. At 5 m. a mearing was held in the Philadelphia General Hosp. m. a meeting was held in the Philadelphia General Hospital, at which addresses were made by Dr. Joseph S. Neff, Dr. Charles K. Mills, Dr. Alfred Stengel, and Dr. George W. Guthrie, of Wilkes-Barre, Pa. Luncheon was served at the close of the meeting. In the evening a "smoker" was held at the Bellevue-Stratford.

Association of Military Surgeons of the United States.

The seventeenth annual meeting of this association will be field in Atlanta, Ga., on October 13th, 14th, 15th, and 16th, Delegates will be present from Great Britain, India, Mexico, Portugal, Ecuador, San Salvador, and Turkey, as well as from nearly every State in the Union. A splendid well as from nearly every State in the Union. A splendid programme has been prepared, and the prospects are good for a very successful meeting. The officers of the association are: President, Assistant Surgeon General George Tully Vaughan, Public Health and Marine Hospital Service, Washington, D. C.; first vice president, Rear Admiral Presley M. Rixey, United States Navy, Washington, D. C.; second vice president, Colonel Joseph K. Weaver, National Guard of Pennsylvania, Norristown, Pa; third vice president, Colonel William C. Gorgas, United States Army, Ancon, Canal Zone, Panama; secretary, Major James Evelyn Pilcher, United States Volunteers, Carlisle, Pa; treasurer, Major Herbert A. Arnold, National Guard of Pennsylvania, Ardmore, Pa; assistant secretary, Captain J. Carlisle De Vries, National Guard of New York, Watkins Glen, N. Y.

Society Meetings for the Coming Week:

Watkins Glen, N. Y.
Society Meetings for the Coming Week:

Monday, October 12th.—New York Academy of Medicine
(Section in Neurology and Psychiatry); Society of
Medical Jurisprudence; New York Ophthalmological
Society; Society of Alumni of St. Mary's Hospital,
Brooklyn; Corning, N. Y., Medical Association;
Waterbury, Conn., Medical Association.

TUESDAY, October 13th.—New York Academy of Medicine
(Section in Public Health); Medical Society of the
County of Schenectady, N. Y.; Practitioners' Club of
Iersey City, N. J.; Medical Society of the County of
Rensselaer, N. Y.; Buffalo Academy of Medicine (Section in Medicine).

Rensselaer, N. Y.; Buffalo Academy of Medicine (Section in Medicine).

Wednesday, October 14th.—New York Pathological Society; New York Surgical Society; Medical Society of the Borough of the Bronx, New York; Alumin Association of the City Hospital, New York; Brooklyn Medical and Pharmaceutical Association; Richmond County, N. Y., Medical Society.

Thursday, October 15th.—New York Academy of Medicine; German Medical Society, Brooklyn; Newark, N. J., Medical and Surgical Society; Æsculapian Club of Buffalo, N. Y.

Erday, October 16th.—New York Academy of Medicine

Friday, October 10th.—New York Academy of Medicine (Sections in Orthopædic Surgery and Pædiatrics); Clinical Society of the New York Postgraduate Medical School and Hospital; East Side Physicians' Association of the City of New York; New York Microscopical Society; Brooklyn Medical Society.

Meetings of Sections of the New York Academy of Medicine.—A nuecting of the Section in Public Health will be held on Tuesday evening, October 13th. The paper of the evening will be read by William H. Allen, Ph. D., secretary of the Bureau of Municipal Research, on The Duty of the Laity and the Profession to Support the Health Department. A general discussion will follow. A joint meeting of the Sections in Pædiatrics and Orthopædic Surgery will be held on Friday evening, October 16th. The general topic for consideration will be paralysis in early life, and papers on the subject will be presented as follows: The Causative Factors, by Dr. Royal S. Haynes; Meetings of Sections of the New York Academy of

follows: The Causative Factors, by Dr. Royal S. Haynes; Differential Diagnosis, by Dr. E. G. Zabriskie; Electrical Treatment, by Dr. H. Romeiser; Mechanical Treatment, by Dr. W. R. Townsend; Operative Treatment, by Dr. R. H. Sayre, A general discussion will follow.

A general discussion will follow.

The Health of Philadelphia .- During the week ending September 26, 1908, the following cases of transmissible diseases were reported to the Bureau of Health of Philadelphia: Malarial fever, I case, O deaths; typhoid fever, 95 cases, 13 deaths; scarlet fever, 49 cases, 3 deaths; chickenpox, 14 cases, o deaths; diphtheria, 53 cases, 5 deaths; cerebrospinal meningitis, I case, I death; measles, 13 cases, I death; whooping cough, 8 cases, 4 deaths; tuberculosis of the lungs, 98 cases, 57 deaths; pneumonia, 40 cases, 22 deaths; erysipelas, 3 cases, 0 deaths; puerperal fever, I case, I death; mumps, 2 cases, 0 deaths; cancer, 19 cases, 22 deaths. The following deaths were reported from other transmissible diseases: Tuberculosis, other than tubercularistic for the larger of deaths. losis of the lungs, 7 deaths; diarrhoa and enteritis, under two years of age, 32 deaths. The total deaths numbered 399, in an estimated population of 1,532,738, corresponding to an annual death rate of 13.50 in 1,000 of population. The total infant mortality was 105; 81 under one year of age, 24 between one and two years of age. There were 29 still births; 16 males and 13 females. The total precipitation amounted to a trace only. The thermometer recorded a maximum of 83° on the 25th.

Charitable Bequests.—By the will of Marie Mayer,

who died recently in Philadelphia, St. Christopher's Hospital for Children, the Maternity Hospital, the German Protestant Home for the Aged, the Evangelical Home for the Aged, the Orphans' Home, and the Asylum for the

the Aged, the Orphans' Home, and the Asylum for the Aged become reversionary legates.

By the will of Mary A. Leighton, the sum of \$10,000 is bequeathed to the Malone, N. Y., Hospital Association, to be known as the Leighton Endowment Fund.

By the will of Winfield Tucker the Presbyterian Hospital, New York, receives \$22,500, to endow three beds in memory of Joseph, Isabella, and Adeline Tucker; the Fresh Air and Convalescent Home at Summit, N. J., receives \$3,000, to found a bed; the New York Postgraduate Hospital receives \$5,000; New York Throat, Nose, and Lung Hospital receives \$5,000; and the House of Rest for Consumptives, Inwood-on-the-Hudson, receives \$5,000.

Hospital receives \$5,000; and the House of Rest for Consumptives, Inwood-on-the-Hudson, receives \$5,000.

By the will of Mrs. Emma A. Tillotson, who died in New York on September 12th, St. Luke's Hospital receives \$5,000 to endow a bed for patients "who have been engaged in the profession of journalism." To each of the following institutions also the sum of \$5,000 was bequeathed: New York Society for the Relief of the Ruptured and Crippled, the New York Skin and Cancer Hospital, the Woman's Hospital, St. Mary's Free Hospital for Children, and the Home for Incurables.

By the will of James R. Savre, Jr., the Hospital for Women and Children, Newark, N. J., receives \$40,000, and the Newark Female Charitable Society receives \$20,000.

By the will of Henry Suydam Wilson, who died in New York on September 23d, the Presbyterian Hospital, New York, receives \$10,000.

York, receives \$10,000.

By the will of Mrs. Mary A. Shaw, the Flushing Hos-

pital receives \$1,000.
By the will of Juliette W. Murray, who died recently in Greenwich, Conn., the Methodist Episcopal Hospital, Brooklyn, N. Y., receives \$5,000, and the Greenwich General Hospital receives \$10,000.

B. the will of Christopher Benfield Carter, K. C. of Montreal, the Montreal General Hospital receives \$5,000, the Protestant Insane Asylum at Verdun receives \$1,000,

and St. George's Home receives \$500.

By the will of a German banker, named Sampson, the Prussian Academy of Sciences, of Berlin, receives

\$7,500,000. By the will of Daniel Martin, St. Vincent's Home for Orphan Children, of Philadelphia, receives \$14,000.

Bith of Current Titerature.

BOSTON MEDICAL AND SURGICAL JOURNAL. October I. 1908.

Acute Appendicitis in Children, By Beth Vincent.
Mechanical Treatment of Diseases of the Circulatory
System with Special Consideration of Zander's Meth-

ods, By C. Hermann Bushholz.
3. Final Report of a Case of Stocker-Adams Disease,

By HERMAN F. VICKERY. 1. Acute Appendicitis in Children.-Vincent reports one hundred cases of appendicular inflammation in children, the ages ranging from two to twelve years. Twenty of the cases occurred in children under five years, sixty from five to ten years, and twenty from ten to twelve years, the age limit of the hospital. Fifty-two of the cases occurred in boys and forty-eight in girls. From a surgical point of view, children over ten years of age resemble adults very closely, and appendicular inflammation between this age and puberty differs but little from the same disease in adolescence. Under ten years the influence of the child's lack of mental and physical development is apparent, and this gives rise to certain characteristics that are normal for a child, but which differ materially from an adult. The younger the child, the more marked are these characteristics or peculiarities. In the one hundred cases, perforation or gangrene was found in seventy-one per cent. The resulting peritonitis was of limited extent in twenty-five cases, but apparently spreading at the time of operation. In forty-two cases the peritonitis had become a localized process that varied from the palpable, firmly walled abscess to the case which had a small amount of pus limited by light but efficient adhesions. The disease was confined to the appendix in twenty-four of the cases. Nine could be called instances of diffuse or general peritonitis. All the adult forms of appendicitis are seen in children, the catarrhal, the gangrenous, the perforative, the suppurative, where the infection is either altogether within the appendix or where the peritonæum has become involved with the formation of a circumscribed abscess, a spreading, or a diffuse peritonitis. The advanced and severe forms, however, are more frequently met with in children, gangrene and perforation being especially common. The catarrhal form and the suppurative form, where the disease is confined to the appendix—empyema of the appendix-are, unfortunately, not so often found at operation as in adults. This peculiarity of children may be accounted for in two ways: first, because the difficulties of early diagnosis lead to a tardy recognition of the disease and to delayed operation; and, second, because the progress of this disease is unusually rapid in the child. The reason for this rapid progress some writers believe is due to the abundance of lymphoid tissue that exists in a child's appendix. A septic process flourishes in this tissue, as, for example, is seen in the child's throat, which is also rich in lymph follicles and where amygdalitis and adenitis so frequently end in suppuration. Light attacks of appendicular inflammation are readilv overlooked. The early stages of the more severe attacks seem to be of short duration. The process tends to extend quickly to the peritonæum, and the

appearance of pus is an early feature. This extension is usually followed by abscess formation, because the child's peritonæum, up to a certain point, is capable of prompt resistance; hence in children one finds a large number of cases of circumscribed peritonitis. If the average time of operation were as early in children as in adults, probably the per-centage of these localized cases would be even greater in children. The author concludes that acute appendicular inflammation is rare in infancy. but is more common in childhood than is supposed. An early diagnosis is difficult, and the first stages and lighter forms of the attack may be easily overlooked. The prognosis of the disease is more rapid in children than in adults; the involvement of the peritonæum and the appearance of pus are early features; diffuse peritonitis is probably more frequent, but there is still greater tendency to the formation of a localized abscess. A child is never so young and seldom so sick as to contraindicate surgical interference, but the extent of the operation must always be measured by the condition of each patient. Children stand short operations well, but may be needlessly lost through prolonged and ill advised efforts to do more than is absolutely essen-The prognosis is more uncertain in children than in adults. Age is a very important factor. In children over ten years of age the prognosis is at least as good as in adults; in children under five years it is worse, and in infants the prognosis is exceedingly grave.

2. Prolapse of the Rectum and Sigmoid Flexure following Hysterectomy.-Hirschman reports two such cases and observes that in patients requiring hysterectomy who give a history of chronic constipation, the possibility of postoperative prolapse of the rectum and sigmoid should be borne in mind, while in patients with a history of chronic constipation who require hysterectomy it must be remembered that the removal of the uterus deprives the rectum of an important anterior support, and the broad ligaments should be brought together whenever possible. In these cases, perineorrhaphy and posterior colporrhaphy should be performed when laceration or rectocele exists. When any tendency to prolapse of the rectum or sigmoid is observed mesosigmoidopexy should be done as a prophylactic

measure. Mesosigmoidopexy should be the operation of choice in every case of complete prolapse of the rectum and sigmoid, whether following hysterectomy or from other causes, as it holds the sigmoid in place by its natural support, its own mesentery, which being double its original thickness becomes twice as strong a support. By not causing a fixation of the bowel to the abdominal or pelvic wall, its natural mobility is not interfered with, and the normal peristaltic movements are not interfered

3. The Surgical Importance of Cervical Ribs to the General Practitioner.—Roberts reminds us that the usual cervical rib is attached to the transverse process and perhaps the body of the seventh cervical vertebra and may be found on both sides of the neck. When the condition is bilateral, one rib is frequently longer and better developed than the other. Occasionally both the sixth and seventh vertebræ are furnished with these irregularly shaped costal appendages. A cervical rib generally approaches in some degree the outline of a dorsal rib. Its attachment to the spinal column, if it is so attached, is also like that of dorsal ribs. It is, however, quite often a very distorted representation of a rib. Its anterior end may be attached to the sternum, may articulate with the upper surface of the first dorsal rib, or may lie in the soft tissues without any other osseous connection than that which it has with the spine. Sometimes the middle of the rib is a fibrous cord uniting a posterior or vertebral bony segment with an anterior bony segment, which may be fastened to either the sternum or the first dorsal rib. In other cases there may be a posterior and an anterior bony segment with no intervening fibrous or bony tissue to represent the shaft or body of the rib. The irregularity of the curves of and the knobs on the anomalous rib may be extreme. Many persons with cervical ribs suffer no discomfort from them, and their existence is unknown unless discovered by some chance clinical investigation. The symptoms are due to pressure on vessels and nerves. The determining cause of the advent of symptoms is obscure. It has been supposed that there is a tendency toward the third decade of life for cervical ribs to grow in length, or to increase in size by the development of exostoses. Those ribs which extend directly outward from the spine appear to cause less trouble than those which project downward and forward. The short, stumpy bones seem to produce symptoms more readily than the longer ribs. This is perhaps due to the fact that the more perfect the shape of the rib the more it and adjacent structures conform to physiological standards and needs. The treatment is excision of the anomalous cervical rib in all cases of severity. The operation, if done well, is practically free from danger, though it naturally varies in its surgical importance in each case. The entire rib should, as a rule, be removed. Subperiosteal resection is not wise, as a regenerated rib may exert pressure again. Injury to vessels, nerves, and pleura is to be deprecated and may usually be avoided by the common expedients available to operators. Pneumothorax, local and general palsy of the extremity, and troublesome bleeding have been caused in some operations. These mishaps are unusual. The palliative treatment in mild cases consists in

rest of the arm, suspension of the patient, local counterirritation, liniments, and massage. The constant electrical current (8 to 10 milliampères) may be employed, with the anode used as the active electrode. The combined faradic and galvanic current may be found useful.

6. A New Position for the Diagnosis and Treatment of Diseases of the Rectum and Sigmoid Flexure.—Hanes describes his method as follows: The author uses a surgical chair or table, such as is used for gynæcological examinations, although a special table is now constructed that can be more easily manipulated. The patient is placed on the table with the footrest dropped, and is allowed to hang over the end of the table on his thighs, with the shoulders resting on the edges of two plain chairs. Or a better position is obtained by allowing the patient to rest his head on a pillow, folding his arms and supporting his weight on each elbow. The author has often kept patients in this position for from ten to twenty minutes with comparatively no discomfort to them. As soon as the patient assumes this position the abdominal viscera gravitate toward the diaphragm, and the maximum tension on the sigmoid and rectum is obtained. The bowel thus approaches the direction of a straight line. This accomplished, the proctoscope is readily passed by the folds and flexures of the intestine, there being absolutely no injury to the mucosa if the distal end of the instrument is kept in view and guided around these natural obstructions. If there are abnormalities existing in the bowel, and it is impossible to pass the instrument by them, they can be observed, and, therefore, no injury done to the patient, which cannot always be assured when other positions are used. The chief advantage in this position is in the fact that the viscera descend most completely towards the diaphragm, and the atmospheric pressure is correspondingly increased. The bowel is ballooned a greater distance along its course, often extending, in normal conditions, along the entire rectum and greater part of the sigmoid flexure. Unless the bowel is ballooned beyond the distal extremity of the proctoscope, an examination with this instrument is of little value. With the patient in this position either the proctoscope or sigmoidoscope may be safely and readily introduced, and the bowel will be distended beyond the distal end, exposing the mucosa distinctly to view. All examinations with tubular instruments are unsatisfactory if the patient is straining; in this position this difficulty obtains less frequently than in any posture that can be employed.

- 1. The Serum Treatment and the Prognosis, under Various Forms of Therapy, of Cerebrospinal Fever.-Koplik has treated thirteen patients with Flexner's serum, in cerebrospinal fever. The ages of the patients varied from three and one half months to five and one half and eleven years; three were below one year of age, and three were two years of age or younger, two of whom are under observation, while two died; the remainder recovered with the exception of one, who was discharged improved. Dr. Koplik thinks it would be rather premature and unfair in every way to draw any conclusions as to the serum until we have seen a larger material and until we have tried it in an epidemic of the violent type, such as we passed through in 1904 and 1905. On the other hand, it may be said that the serum of Flexner not only makes a very favorable impression, but is certainly a factor which cannot be excluded from the therapy of cerebrospinal meningitis, no matter what our subsequent conclusions may be. It certainly does appear that with the serum as we perfect it we may have an improvement in the percentage of recov-
- Pneumonia on the Isthmus of Panama.-Deeks concludes that quinine in large doses in pneumonia is contraindicated on the isthmus of Panama. The drugs at present made use of in the treatment of pneumonia may be said to be at the onset (if much pain is present) 1/4 of a grain of morphine hypodermically; tincture of ferric chloride in 1/2 drachm doses three times daily. This is done because of the marked anæmia which has hitherto characterized the patients there, due in great part to intestinal parasitism and poor food. Strychnine and nitroglycerin hypodermically, as much as 1/30 grain of the former and 1/100 grain of the latter, may be given as frequently as every three or four hours, and whiskey ad libitum. It has been given when there was a great deal of toxemia up to 18 ounces in twenty-four hours. Much less (6 or 8 ounces daily) is generally given toward the end of the disease. In mild cases no medication at all is necessary, but in severe cases the pulse must be frequently watched, and the stimulants varied accordingly. As a rule, nothing is necessary the first three or four days; then stimulation is begun as the symptoms or condition of the patient indicate. During the course of the affection an occasional dose of magnesium sulphate is considered good treatment, particularly if constipation is present. In extreme cases saline enemata are of great value, apparently often tiding the patient over a crisis. These may be given in quantities of 6 or 8 ounces every three hours, particularly if the patient is not taking nourishment well. As a rule they are retained. If the case is a very toxic one, a gallon or more of warm physiological saline solution is used to lavage the bowels. In other words, the treatment practised on the isthmus of Panama is supportive and eliminative, and in the class of patients that the author has to treat, with their numerous complications, the results on the whole must be considered at least satisfactory
- 4. Early Tuberculosis and Malaria; Their Distinction. Ringer remarks that the diagnosis may be considered under three distinct headings: (1) Clinical symptoms, (2) laboratory findings, and (3)

therapeutic test. 1. Clinical symptoms.—In both diseases we may have actual chill, or chilly sensations, but a definite rigor speaks far more in favor of malaria than of tuberculosis. A common symptom of both diseases, usually higher in malaria than in early tuberculosis, and rising suddenly in malaria as compared with a gradual ascent in tuberculosis. A carefully kept two hourly temperature record is one of the best means of distinguishing the two diseases. In malaria the fever usually drops by crisis; in tuberculosis by lysis. However, in the æstivoautumnal type of malaria, fever may last more than twenty hours (this not occurring in early tuberculosis) and fall by lysis—the fever in this type of malaria may even be continuous, the picture then being suggestive of typhoid fever rather than tuberculosis. Sweating is far more profuse in malaria than in early tuberculosis, where real sweats are uncommon. Drenching sweats occur only in the more advanced cases of tuberculosis; in malaria they may occur after every paroxysm of fever. A most important point in his opinion is the fact that between paroxysms the malarial patient feels wellthe tuberculous patient feels sick. The malarial patient (unless he is the victim of an old chronic malarial poisoning) recovers swiftly from his paroxysm. The tuberculous individual is constantly a prey to the tuberculotoxines, and consequently feels weak and below par all the time. Bronchitis may be a symptom in both diseases— in malaria is usually diffuse and at the bases of the lungs posteriorlyin early tuberculosis often sharply localized and at an apex. Breath sounds are of paramount importance, particularly in the epical region. With an afternoon fever, whether preceded by a feeling of chilliness and followed by a sweat or not, if at one apex the breathing is roughened as compared with that of the opposite apex, whether expiration be prolonged or not, a diagnosis of incipient pulmonary tuberculosis is so probable as to be justifiable. Dullness and râles need not be awaited; they occur when the tubercles have coalesced and when bronchitis has set in. Rough breathing denotes discrete tubercles. Careful auscultation above the clavicles, and particularly in the first intercostal space close to the sternum, is a sine qua non for the earliest possible diagnosis of pulmonary tuberculosis. Splenic enlargement is usually present at some time in malaria -not found in tuberculosis. Herpes labialis is not seen in early tuberculosis. 2. Laboratory findings. -The blood and sputum should be carefully and (if negative) repeatedly examined in making this distinctive diagnosis; if all examinations are negative, if there is ever so slight a change in the breath sounds at one apex, if intermittent fever and general malaise persist, the case is one of tuberculosis and not of malaria. 3. Therapeutic test.—Osler has given us an axiom, "An intermittent fever that resists quinine is not malarial." Therefore, if needs be, let quinine be exhibited; if the patient recovers, malaria was present; if not, malaria can be excluded. Stress should be laid upon the fact, particularly in malarial districts, that tuberculosis may set in with fever typically intermittent in character, and daily chill with subsequent fever and sweat; but careful note of the points mentioned should clear up the ætiology of the febrile movement.

5. Surgical Shock.—Mummery and Symes have studied the prevention and control of the vascular atony of surgical shock, and summarize their conclusions as follows: In fully anæsthetized animals nondestructive manipulations of abdominal viscera are more productive of shock than are gross injuries. Such manipulations produce shock most rapidly when they implicate the parietal peritonæum, the peritoneal ligaments, or the mesenteries. Shock is more readily produced under chloroform than under ether. In severe shock hypodermic injections are but slowly, if at all, absorbed into the blood stream. In severe shock intravenous injections of adrenin, and of extract of the posterior lobe of the pituitary body, raise arterial pressure to a greater extent than in the normal state. A single injection of the latter influences arterial tone for upwards of an hour without producing abnormally high arterial pressure. This influence is sufficient to enable considerable recovery from shock, and does not interfere with subsequent injections of adrenin, if that is desirable.

7. Suprarenal Glands and Osteomalacia .--Bossi reports the case of a woman, seven months' pregnant and suffering from an extreme degree of osteomalacia. She suffered most severely from the usual symptoms-pain, difficulty in walking, anæmia, osteomalacic cachexia, and insomnia. As the pelvis contracted her torture became extreme. Because of the ischæmic effect of adrenalin, and because of the demonstrated relations between the ovaries and suprarenal glands, adrenalin was given in doses of 0.5 The pains immediately began to disappear, the pelvis dilated, and the patient was spontaneously delivered of a normal child at term. A second pregnancy was unaccompanied by any signs of osteomalacia. The writer thinks he has not only discovered a new method of treating osteomalacia, but also evidence that (I) insufficiency in the function of the suprarenal glands must be the cause, or a factor in the causation, of osteomalacia; (2) the suprarenal glands exercise an important influence on the ossification of the skeleton. If these results are confirmed the ossification of the skeleton in rickety children should be accelerated by the administration of adrenalin.

10. Scopolamine in Labor.—Krönig believes that scopolamine, given in conjunction with morphine, surpasses all other anæsthetics in labor, producing the so called "dawning sleep." A three hundred per cent. solution of scopolamine hydrobromide and a one per cent. solution of morphine are used. The first injection consists of 4.5 decimilligrammes of scopolamine and I centigramme of morphine. It is given when the patients have pains lasting at least thirty seconds, and which recur at regular intervals of four or five minutes. The first effects are generally manifest about half or three quarters of an hour later. The patients become sleepy and slumber between pains, but awake when the pains return. A second injection of from 1.5 to 3 decimilligrammes of scopolamine alone is given an hour after the first. Half an hour later the perceptive capacity of the patient is tested by asking her if she recognizes an object previously shown her half an hour before, or if she remembers how many injections she has had. If she fails to meet these tests, no further injection is needed. As a rule, all injections following the first contain scopolamine only. Patients may thus be kept semiunconscious for twenty-four hours. After a successful "dawning sleep" women awake post partum perfectly happy, and declare they have felt nothing. It frequently happens that they will not believe they have been delivered. Everything depends on the correct dosing of scopolamine, and the only available standard as to the correctness of the dose is the test of the patient's consciousness. Loud noises, strong lights, etc., are a considerable drawback in achieving good results. The author's conclusions are based on his esperience in 1,700. cases. The length of labor is only immaterially increased, and the method is certainly without danger to the mother, and probably without danger to the child. Of the 1,700 women only two died soon after confinement, and neither of the deaths could be

in any way attribued to the scopolamine. It can be used even in cases of organic heart disease.

22. Neurasthenia and Hysteria.—Schofield regards the psychological distinction between neurasthenia and hysteria as profound. In neurasthenia there is an exhaustion or poisoning of the higher cerebral or spinal nerve centres. In hysteria there is no question of exhaustion, but there is aberration and morbid action of that part of the unconscious mind (vis medicatrix naturæ) which presides over the functions and nutrition of the body, and which produces in hysteria, unconsciously and against the patient's will, morbid phenomena which the mind consciously is wholly unable to produce even if it wished -as, for instance, reversed peristalsis, high temperature, local tumors, etc. Hysteria is thus parallel to insanity, though quite distinct from it; the radical difference being that the sphere of the former is the unconscious and that of the latter the conscious mind.

Anæmia and Thrombosis. - Hawthorne maintains that the interpretation of the cerebral and ocular complications that occasionally occur in cases of anæmia in women is to be found in the intravascular formation of blood clot. Among the special characters pertaining to the anæmic state there must be included an undue tendency to blood coagulation, at least as long as the blood is contained within the bloodvessels. When withdrawn from the vessels, however, the opposite condition obtains, coagulation being both delayed and incomplete. An important and determining factor in the thrombosis of anæmia is a delayed or sluggish rate of blood flow. Not only certain acute and serious complications, but also a number of comparatively minor disturbances in anæmic women owe their origin to intravascular blood clotting. Such disturbances are more frequent than is generally supposed, and are warnings or danger signals of the possibility or even the probability of clot formation, on a large scale or in dangerous situations. They thus claim the special therapeutic measures by which disastrous results may be averted. The most frequent and obvious exhibition of thrombosis in anæmia is met with in the large veins

of the lower limbs. The symptoms include pain, tenderness, and cedema, with or without fever. The thrombosis may extend from the femoral to the iliac veins, and even to the inferior vena cava. It is rare for the veins of the upper limbs or of the neck or chest to be involved, but they are not exempt. Apart from embolism, the prognosis in these cases is far from gloomy, and the circulation in the veins may be completely restored. So that an obstructing clot formed in a vein in association with anæmia may, presumably by absorption or organization, be completely removed. Similar anæmic thrombosis sometimes occurs in the intracranial veins and sinuses. The symptoms are severe headache, vomiting, pain in the neck, retraction of the head, stupor, delirium, various paralyses, and sometimes double optic neuritis. A diagnosis of intracranial tumor or meningitis may be made, but most of the cases are examples of venous thrombosis within the This diagnosis is sometimes supported by the development of thromboses in other situations. Another consequence may be a limited paralysis of one or other of the ocular muscles. Neither a difficulty in providing a manifest explanation of the mechanism by which sinus thrombosis may produce optic neuritis; nor the statement that the frequent. absence of general cerebral disturbance with such neuritis opposes the diagnosis of intracranial thrombosis: nor the observation that in arterial thrombosis optic neuritis does not occur; nor the comment that the neuritis disappears under treatment with iron—is found, on examination, to present any insuperable objection to the proposition that optic neuritis occurring in anæmia has, in all probability, its explanation in the formation of blood clot in the veins or sinuses of the brain. Retinal embolism is an event of occasional occurrence in anæmia and also demands thrombosis as its interpretation. Retrobulbar neuritis also occasionally occurs as a complication in anæmia, and is possibly due to thrombosis. In its typical form this is characterized by sudden loss of central vision in one eye without evident ophthalmoscopic change. These facts demand a lesion in the trunk of the optic nerve posterior to the eyeball, and the suddenness of the lesion often suggests that it is vascular in nature. In the practical sphere, the suggestion that optic neuritis, ocular paralyses, hemianopsia, or other abnormalities of the visual field, retinal embolism, or retrobulbar neuritis, occurring in anæmic patients, are probably due to thrombosis, is significant, because on such interpretation any one or more of these events appearing in an individual case must be accepted as the sign of a tendency to thrombosis in an unusually marked degree, and must therefore claim the application of the therapeutic measures which such a conclusion demands.

8. Anæsthetics.-Hewitt states that there are three main principles which must collectively be observed in order to secure safe anæsthetization. These are: (1) The selection of appropriate anæsthetics according to the exigencies of particular cases; (2) the adjustment of the vapor percentage of the anæsthetic to meet the varying requirements of each case; and (3) the avoidance of the slightest obstruction to the free entry and exit of air throughout the administration. The third principle is the most important, as some obstruction above the trachea is usually a powerful factor in the great majority of deaths under anæsthetics.

I. Stercobilin. Fæcal Urobilin,

By A. GILBERT and M. HERSCHER. 2. On Which Side do Patients with Pulmonary Tuberculosis Sleep, Relatively to the Seat of Their Lesions?

Stercobilin.—Gilbert and Herscher studied first the methods of extraction of stercobilin, of its chromogen and of the biliary pigments from the fæces, then the biliary pigments stercobilin and stercobilinogen in the physiological fæces of adults and of infants, then the same pigments in pathological fæces, the method of formation of stercobilin and stercobilinogen, the physiology and pathology of the biliary excretion, and the semiological value of stercobilin. They assert that neither urobilinuria nor the presence of stercobilin indicates any hepatic insufficiency, but that, on the contrary, its suppression or diminution, or the addition to it of stercoral bilirubin, shows a defect in the biliary secretion or excretion.

LA SEMAINE MEDICALE

September 2, 1008

Contribution to the Study of Grave Pseudoparalytic By G. MARINESCO. Myasthenia. Simplification of the Technique of the Serodiagnosis of Syphilis.

By J. BAUER.

Myasthenia.-Marinesco says that myasthenia is characterized clinically by fatigue and exhaustion of the voluntary muscles, chemically by an insufficiency of oxygenation, shown especially in the voluntary movements, and consequently the appearance of intermediary products, the destruction of the chemical composition of the muscle, and the augmentation of the total azote in the urine; pathologically by changes in the striated muscles and in many of the glands with internal secretion, such as the parathyreoid glands, the liver, the suprarenal capsules, and the hypophysis. The latter and perhaps the parathyreoid glands present microscopically the picture of glands in hyperfunction. As regards the primum movens of the disease, this seems to reside in a perturbation of the formation of the antibody of fatigue, or of the oxydases.

- By ERNST BARTH. Outline of the Modern Care for Cripples By BIESALSKI.
- 2. History and Treatment of Tuberculosis .-Klebs concludes that immunizing, or, better, cell protecting, substances, sozines, such as the tubercle sozine, should be used when the onset of fever indicates the setting free of tubercle bacilli from the foci in the organs, also when their presence in the lungs can be demonstrated by quantitative determination of tubercle bacilli in the sputa. It may be that in such cases serological experiments should be made, because the serum or the fluid of the exudate forms a deposit with the culture fluid of tubercle bacilli in acute extension of the tubercle bacilli. When the use of the tubercle sozine is ineffective, an injection with Möller's blind worm tuberculosis should be made. Usually this causes no fever and no suppuration, but in very infectious cases it produces a characteristic formation of papules of slightly reddish hue with exfoliation of the skin during recovery. The course of the papule seems to be of particular prognostic value. formation of tubercles and swelling of the neighboring lymphatic glands are never produced by the pure preparations. Another very important use of the blind worm tuberculosis is in incipient tuberculosis, or scrofulosis, especially in children when the swellings of the lymphatic glands first appear. This is to be recommended, particularly in tuberculous families. It is advised to make the injection either in the back, at the inner end of the spine, or the scapula, when lung affections are present, as is usually the case, or higher in the cervical muscles, or in the sternocleidomastoid, according to the position of the swollen glands. The injections should be made into the tissue of the muscles, the needle being introduced vertically through the skin.
- 5. Paraffin Protheses.-Stein asserts that paraffin melted with petrolatum should not be used for subcutaneous protheses, because the melting point of such a mixture cannot be ascertained with sufficient accuracy. Cold paraffin with a melting point

under 50° C. should be employed; it remains to be determined how far below 50° C. the melting point

6. Toxine and Anaphylactic Substance of Eel Serum.-Dörr and Raubitschek state, I, that poisonous sera, particularly eel serum, contains two kinds of antigen, toxine and anaphylactic bodies. If the former is destroyed by heat or acids, even the death of the anaphylactic animal may be brought about by the changed nonpoisonous product; 2, the immune bodies, antitoxine and anaphylactic reaction bodies arise in the serum independently of one another; 3, if they are all present together such an immune serum forms a preventive protection against fatal quantities of the poisonous albumin, on the other hand becomes anaphylactic toward larger doses of the same kind of albumin artificially robbed of its toxicity.

8. Singers' Nodules .- Barth declares that the nodules formed on the vocal cords of singers are due to a faulty technique of singing and that treatment is without value until the technique is cor-

- 2. Paratyphus.—Bingel reports twelve cases of paratyphus. The Bacterium paratyphi was cultivated from the stools of almost every patient. From many stools a stock was cultivated and a careful bacteriological analysis instituted, experiments were made on animals and agglutination tests made. Clinically paratyphus presents the picture of a mild or moderately severe gastroenteritis without organic changes. Characteristic are the suddenness of the onset of the symptoms, the marked influence upon the general condition of the gastrointestinal symptoms, and the nevertheless mild and favorable course
- Technique of the Wassermann-Neisser-Bruck Serum Diagnosis of Syphilis.—Tage gives the technique of this investigation very fully, but not in a manner readily to be abstracted. It is worthy of note, however, that at the end, in the final determination whether a certain serum is that of a syphilitic or not, difficulties are to be met with. If the fluid in the test tube is clear red the serum is normal, if it is colorless it is that of a syphilitic,

but when the coloring is between these two extremes doubt arises and only an experienced eye can decide to which it belongs. He also states that in the process there is a number of sources of error which can scarcely be avoided by the most extreme care.

7. Operations for Hernia under Local Anæsthesia .- Nast-Kolb states that during the last seventeen months he has operated under local anæsthesia on sixty-three free inguinal hernias, nine free femoral hernias, two incarcerated inguinal, seven incarcerated femoral hernias, two of the latter with resection of the gangrenous intestine, and, in addition, four umbilical and seven epigastric hernias. He used a one per cent. solution of novocain and considers the method to be decidedly advantageous.

10. Boric Acid Treatment of Suppuration of the Middle Ear .- Dölger finds that different preparations of boric acid differ extraordinarily in their solubility in water, corresponding probably to the differences in price of the various qualities of the drug, and that more attention should be paid to the purity and solubility of the boric acid for thera-

peutic use.

11. Another Case of Eye Disease from an Artificial Fertilizer.—Hessberg reports a case met with in a man sixty-three years of age, in whom an extremely virulent inflammation of the eye, resembling panophthalmitis, was induced by a little artificial fertilizer being blown into it while the man was spreading it over the ground. The eye was burned only a little by the superphosphate, but two days later the inflammation was very severe, involving all the tissues of the anterior section of the eve, and resulted in the total loss of the eve.

12. Cyst Formation in the Remains of the Vermiform Appendix.—Lean reports a case of this nature met with in a woman twenty years old, who had recovered from an attack of appendicular

inflammation eight years before.

The Pathological Anatomy of Bronchial Asthma By A. G. Ellis. 10. Henry Gray, Anatomist. An Appreciation.

By F. K BOLAND 1. The Relations of the Female Reproductive Organs to Internal Diseases.-Müller thinks a consideration of this question should mention (1) the internal diseases which have been observed in connection with the physiological processes of the female generative organs, including puberty, pregnancy, and the menopause; (2) the significance of the pathological processes in those organs which give rise to medical conditions; (3) the relation of certain internal diseases to disorders of the female reproductive apparatus. Puberty signifies much more disturbance in the female than in the male. Suggestive conditions are chlorosis, thyreoid enlargement, and psychic changes. Pregnancy, though physiological, often brings many undesirable conditions, including vomiting, neuritis, and various cardiac disturbances. The climacture may bring many disturbances. Of the second group one notes the association with disturbed bowel function, heart lesions, goitre, and various nervous diseases. In the third group diseases of the kidneys and urinary tract are very prominent. Pregnancy often has a very unfavorable influence upon those organs. Ovulation fever, disease of the gallbladder and bile passages, and appendicitis must also be considered in this connection. Of the constitutional diseases diabetes and tuberculosis have an influence on the genital organs which is most marked especially during pregnancy and the puerperium.

2. The Specific Treatment of Typhoid Fever. -Vaughan announces as the result of his investigations that it is improbable that an antitoxine comparable to that which is used in the treatment of diphtheria should be found for typhoid fever. Diphtheria being so essentially distinguished from typhoid fever in the nature of the infection it would be impossible to draw conclusions from one and apply them to the other. There is no satisfactory evidence that the typhoid bacillus produces a soluble poison. The mechanism of immunity is not the same in all infections and intoxications. forms of immunity are possible (1) Antitoxine im munity, in the production of which neither phagocytic activity nor proteid cleavage has any concern. (2) Phagocytic immunity, which shows that with virulent or slightly virulent strains phagocytic activity may be increased, while with highly virulent strains such is not the case. (3) Lytic immunity. which may also be termed bactericidal or bacteriolytic immunity. There is no antitoxine for the typhoid poison. Phagocytic action is not a marked factor in the natural recovery from typhoid fever. and the author proposes to see what can be made out of lytic action in the study of the nature, progress, and recession of typhoid fever.

3. Observations on the Hypodermic Use of Quinine and Urea Hydrochloride in the Diagnosis and Treatment of Acute and Chronic Malarial Infections.-Cohen states that the hypodermic use of this double hydrochloride has been useful in two ways: 1. There are certain cases of acute infection resembling malarial fevers, but in which malarial organisms are not found in the blood. There are other cases in which a malarial origin or complication is suspected, but in which malariai hæmamæbæ have not been discovered. In most of these cases the presence or absence of malarial ininjection of the urea and quinine salt. A prolonged period of freedom from symptoms would indicate

that the previous symptoms were due to undiscovered, perhaps deep dwelling, parasites, while the absence of such a period would mean the absence of malarial infection. 2. In cases of doubtful diagnosis the injection of a quantity of the drug insufficient to secure a definite period of freedom from symptoms may cause the appearance in the peripheral blood of normal or atypical forms of the hæmamoba of malaria. The absence of this fact after half a dozen injections, at intervals of three days to a week, and in doses increasing from 0.3 gramme to 1 gramme will virtually exclude malarial infection.

4. The Resistance of Diabetics to Bacterial Infection.-Da Costa and Beardsley find the following deductions warranted: I. In diabetics the resisting powers of the blood against bacterial infection are subnormal compared with the healthy individual. Measured by the opsonic index the average diabetic's resistance is one third below normal. 2. The higher grades of diabetic glycosuria are attended by a feebler opsonophagocytic action than the lower grades, and the reverse is also true. 3. Diabetic acidosis particularly lowers the blood resistance to the bacillus of tuberculosis, but a less degree of vulnerability exits with regard to the streptococcus and staphylococcus. 4. Diabetic furunculosis does not materially depress the patient's opsonophagocytic powers to the ordinary pyogenic cocci below the figures usually incident to this disease. 5. Diabetics with pulmonary tuberculosis have virtually the same resisting powers as do subjects of uncomplicated diabetes. 6. In nonsaccharin diabetes the opsonic values to the staphylococcus range within normal limits, and this statement also applies to nondiabetic glycosuria.

5. The Blood Pressure in Arteriosclerosis .-Rudolf observes that with thickened arteries the blood pressure is likely to be increased, and in recent years many instruments have been devised for accurately measuring this pressure. The diastolic pressure is that which is of most importance, and the author thinks there is great need of an instrument to meet this want. He arrives at the following conclusions: I. In many cases of even well marked arteriosclerosis the blood pressure is not raised. This may be due to localization of the disease to a part of the arterial tree, or to the fact that the heart may be giving up the struggle, the once high pressure having fallen. 2. In many cases of arteriosclerosis the blood pressure is above normal. 3. In a given case in which the pressure is raised it cannot be assumed that it is high because of the disease of the vessel walls, nor that the sclerosis is due to the increased pressure. The arterial stiffening may be due to syphilis and the hyperpyesis to some intercurrent condition of nervous or toxic nature which may be removable by suitable treatment.

8. Leucanæmia. — Elmer states that certain authors contend that this is only an atypical form of pseudoleuchæmia or leuchæmia, others claiming that it is a clinical entity, a true combination of leuchæmia and pernicious anæmia. A case is narrated, with autopsy, in which the general symptoms resembled pernicious anæmia while the physical signs were the exit plenic or splen involvageneous leuchæmia. The blood picture recombled pernicious anæmia and

myelogenous leuchæmia, the number of young forms being much greater than is present in either leuchæmia or pernicious anæmia. Myelogenous leuchæmia is associated with considerable anæmia and the blood findings usually show normoblasts and some megaloblasts. It is concluded that while leuchanæmia has a definite clinical and hæmatological picture, it is not a separate disease, but the result of some unknown infection which in some individuals would cause anæmia, in others leuchæmia, and in others a combination of the two.

Proceedings of Societies.

SIXTH INTERNATIONAL CONGRESS ON TUBERCULOSIS.

Heid in Washington, D. C., September 28, 29, and 30, and October 1, 2, and 3, 1908.

(Continued from page 669.)

SECTION I.

Variations of the Virulence of the Tubercle Bacillus.—Dr. S. Arloing, of Lyons, said that for twenty-two years he had been testing the varying degrees of virulence of the Bacillus tuberculosis by inoculation and by cultural methods. He found that the guinea pig was easier to infect than the rabbit. He classified the lesions according to the degree of infectiousness. In surgical diseases the virulence of the organisms, according to his experience, was less than in pulmonary infections. In certain cases of true tuberculosis, however, the bacilli were as virulent as any bacilli isolated from pulmonary lesions. There was great variability in the degree of virulence of organisms from the same anatomical source, from a virulence which produced lesions easily cured to the most fatal form of infection. The varying results were ascribed to the variations of the virulence of the organism and not to differences in race, such as bovine and human. Similar experiments in the human and bovine bacilli gave similar results. He concluded that all tubercle bacilli belonged to one

The Routes of Infection in Tuberculosis.—Dr. JULIUS BARTEL, of Vienna, said that in man, as in animals, a lymphoid stage of tuberculosis existed, in which there was a lymphocytic hyperplasia of the lymph nodes, or in which the lymph nodes remained apparently unchanged. Attempts at immunization in the lymphoid stage, followed by attempts at reinfection, showed, first, signs of increased tendency toward infection, then signs of increased resistance to infection, and finally complete immunity; second, processes of complete cure in organs affected, with manifest tuberculous changes; third, mainly manifest tuberculosis of the lungs with the bronchial lymph nodes, and pulmonary cavities; fourth, isolated manifest tuberculous disease of the lungs, the portals of entrance remaining perfectly intact, with all opportunity of direct lung infection having been excluded. So it was seen that under certain conditions tuberculosis was a cryptogenic infection. Similar conditions must have prevailed in human pathology, so that if we only looked for the signs of maniiest tuberculosis during an autopsy we had insufficient evidence to determine the portals of entry. The signs of lymphoid tuberculosis must be considered. Infection from the pharynx, the stomach, and the intestines was far more frequent, particularly during early life, than had generally been supposed.

The Relation of Air to Tuberculosis; Sterilization of the Air.—Dr. Samuel Bernheim, of Paris, said that there was a close relation between the microorganisms of the air and tuberculosis. The greater the number of bacteria in the air the greater would be the number of cases of tuberculosis in the community. In overcrowded districts, in places where meetings were held, in hospitals, in prisons, in schools, in barracks, in great shops, in factories, and in other workrooms the high bacterial contents of the air and the high proportion of tuberculous individuals would be found. In order to get rid of tuberculosis in a given population, the hygiene of houses and the sanitary condition of the towns must be supervised. Goupil's tub and Silbermann's double current chimney were spoken of as assisting in the destruction of air bacteria in all kinds of apartments, particularly in hospital wards, amphitheatres, and other assembly halls.

The Predisposition of the Apices of the Lungs to Tuberculosis.—Dr. CARL HART, of Berlin, said that in the youthful subjects of tuberculosis an individual predisposition might exist, due to anatomical and functional disturbances of the normal relations at the superior opening of the thorax. This disturbance might be congenital, hereditary, or acquired. The predisposition which at first diminished the actual size and the function of the apices favored the deposition of tubercle bacilli and also diminished the natural resistance of the tissues. In this way the localization of the first tuberculous focus in the apex was accounted for, and this local predisposition was equally important whether the infection was brought to the apex with the air, the lymph, or the blood. The final outcome of the struggle between the Bacillus tuberculosis and the tissues depended upon the condition of the resisting power of the latter. Therefore the measures to be employed in combating tuberculosis should be directed, more than had been done in the past, toward the prevention of any anatomical or physiological interference with the apices of the lungs.

Heredity in Consumption.—Surgeon General SIMON VON UNTERBERGER, of St. Petersburg, said that the difference between the infectionists and the hereditarians concerning the origin of consumption was relative rather than actual. For the genesis of pulmonary tuberculosis a soil (the body) and an exciting cause (Bacillus tuberculosis) were necessary. He then referred to the chromosomes formed in the segmenting impregnated ovum, and reminded his audience that one half of them were inherited from the father, and that the other half were inherited from the mother of the individual. He thought that the tendency to consumption was inherited in this way. He referred to the frequency of the demonstration of healed tuberculous lesions in autopsy subjects over thirty years of age, and said that that fact showed how easily the organism could overcome the tubercle bacillus. Therefore the indication for treatment was to strengthen the organism by hygienic and dietic methods. Of course we must

seek to destroy the tubercle bacillus, but it was utopian to expect to destroy all the tubercle bacilli in the world. The chief endeavor, therefore, must be to strengthen the body.

JOINT SESSION OF SECTION I AND SECTION II.

The Opsonic Index in Certain Tuberculous Infections.—Dr. Thomas Wood Hastings, of New York, said he had studied the question of the opsonic index in tuberculosis from the point of view of estimating an opsonic index; from the point of view of the variations of the opsonic index in normal sera and in the sera of tuberculous individuals; from the point of view of the variations in the opsonic index in individuals not under tuberculin treatment; and from the variations in the opsonic index in cases under tuberculin treatment. He found that a low opsonic index was not constant in cases of tuberculosis. The opsonic index, he found, did not correspond to the clinical condition of the patient, and it could not be used as a guide to inoculation. He found that wide variations occurred in the opsonic index over long periods of time, so that to establish the pathological variation the index should be determined at least two or three times a week for two weeks.

The Opsonic Index in the Diagnosis of Pulmonary Tuberculosis .- Dr. GEORGE P. SANBORN, of Boston, exhibited a chart showing the curve of the opsonic index in a case of pulmonary tuberculosis. The patient was observed under conditions of complete rest, during moderate activity, during hard work, and after inoculation with a tubercle bacillus emulsion. The opsonic index was determined twice or three times a day, under these varying conditions, for two months. As a result of these observations it was found that a normal opsonic index was obtained both when the patient was at rest and when he was doing light work. With hard work, however, the opsonic index was increased, showing autoinoculation. The injection of tuberculin (bacillus emulsion) also raised the opsonic index. He thought that if the opsonic index was raised after exercise, in a case of suspected pulmonary tuberculosis, the diagnosis of pulmonary tuberculosis would be warranted.

The Accuracy of the Tuberculoopsonic Test and its Value as a Control to Tuberculin Treatment in Pulmonary Tuberculosis.—Dr. H. M. RINGHORN, Dr. D. C. TWITCHELL, Dr. N. M. CARTER, and Mr. F. W. O. WERRY, of Saranac Lake, N. Y., had made control opsonic tests at various intervals in twenty-three series of a normal serumin all, one hundred opsonic determinations. The tests were made by three different observers, with the result that the mean error of a single observation was found to be plus or minus fourteen, so that that much margin must be allowed in making single opsonin observations in specific instances. In patients who were being treated with tuberculin by the progressive method inaugurated by Trudeau, at three or four day intervals, they found that the opsonic index was raised by the tuberculin injections. In a majority of the tests definite negative phases were followed by definite positive phases. When an injection of tuberculin was given during a negative phase, as often happened when it was administered at such short intervals, the opsonic index was still

further depressed; but a positive phase at once set in. In nincteen per cent. of cases the positive phase had not ceased before the next injection was given, when the four day interval was followed. Although it was impracticable to make an opsonic index every day on every patient, they found that the index was of definite value in spacing the doses; but they doubted its value for the control of tuberculin injections in phthisical patients. The aim of tuberculin therapy should be to produce immunity, not to keep the opsonic index at a high level.

The Tuberculoopsonic Index in the Diagnosis and Treatment of Tuberculosis.—Dr. MARY C. LINCOLN, of Chicago, said that the opsonic index was not a satisfactory guide to the therapeutic employment of tuberculin in the treatment of tuberculosis. Her studies had extended over a period of two years and had included about 200 cases.

The Application of the Cutaneous and Conjunctival Tuberculin Reactions in the Diagnosis of Tuberculous Infections.—Dr. A. CALMETTE, of Lille, said that 92.05 per cent. of patients who were clinically tuberculous gave a positive reaction when the conjunctival test was applied. Fifty-seven per cent. of suspicious cases gave a positive reaction. Sixteen and eight tenths per cent. of apparently healthy persons gave a positive reaction. Of fiftyfive children and adults who had given positive conjunctival reactions, and who were not suspected to be tuberculous, who came to autopsy, macroscopic tuberculous lesions were found in forty-nine, usually in the bronchial lymph nodes. Of the 6,303 patients from whom these figures were compiled, three had phlyctenular keratitis, twenty had conjunctivitis, and seventy-two had a reaction which lasted bevond three weeks. In no case was more serious disturbance or permanent ocular lesion found. In general, early reactions were most trequently observed with suspected tuberculosis, and late and slight reactions with developed tuberculosis. Cachectic patients, patients with acute miliary tuberculosis, tuberculous peritonitis, and hypertoxic tuberculous infections reacted very feebly, late, or not at all. Repeated instillations of tuberculin in healthy subjects never gave a reaction when the intervals between successive instillations did not exceed five days; local excess of susceptibility disappeared in about twenty-five days. As a rule no ocular reaction occurred in patients who were treated with subcutaneous injections of tuberculin until over a month after the interruption of the treatment. In children under one year of age the conjunctival test was preferable to the cutaneous test, and it was also preferable in adults. In hospitals the simultaneous employment of both tests was recommended. A positive result by this double test furnished almost conclusive evidence of the existence of active tuberculous disease.

Experiences in the Cutaneous Tuberculin Reaction in Two Hundred Children, with Autopsy Results in All.—Dr. C. von Pirquet, of Vienna, said that 200 of the 1,600 children in the two Vienna children's hospitals, who had been subjected to the cutaneous tuberculin reaction, died and were carefully dissected. Sixty-eight of these children had ican a positive reaction, and sixty six of them I careful is created in created and person of them.

the two patients that failed to show macroscopic tubercles had pleuropericardial adhesions. He concluded that a positive cutaneous reaction indicated infection with tubercle bacilli. Negative reactions were found in 109 of the remaining cases that came to the autopsy table. A negative reaction was also found in several cases of fatal tuberculosis, particularly in older children, when the test was made a few days before death, and in some cases of tuberculosis in which the test was made during an attack of measles.

The Early Diagnosis of Tuberculosis.-Dr. WOLFF-EISNER, of Berlin, said that percussion was the most valuable clinical method in the early diagnosis of tuberculosis. A high percentage of lymphocytes in an exudate pointed to a tuberculous lesion, and lymphocytes in the sputum were an important early symptom of tuberculosis, as they appeared betore tubercle bacilli. The clinical value of the subcutaneous injection of tuberculin was relatively slight, because it showed latent as well as active tuberculosis. The same objection applied to the cutaneous reaction; but it was devoid of danger, and a negative result was of considerable diagnostic value. The conjunctival reaction gave positive results in the presence of active tuberculosis only. Positive results were obtained in eighty-five per cent. of all cases of active tuberculosis in the initial stage, and only twenty-five per cent. of apparently healthy individuals reacted positively. In a number of apparently healthy persons who gave a negative conjunctival reaction the existence of active tuberculosis was subsequently demonstrated. He said that the conjunctival reaction was absolutely without danger if the contraindications were observed. Secondary instillations should be avoided; the test should not be made when there was actual or suspected ocular tuberculosis. The reaction failed as the tuberculous process advanced. Failure of the cutaneous and conjunctival reactions was an unfavorable prognostic sign when manifest active tuberculosis was present with tubercle bacilli, but not under any other circumstances. He distinguished (1) a normal reaction, which ran its course in four days; (2) a rapid reaction which was complete in twenty-four hours, and indicated an unfavorable prognosis; and (3) a permanent reaction, which persisted for from six to twenty days, and was a favorable prognostic sign. The permanent reaction was observed chiefly in cases of healed

Conclusions from 1,087 Conjunctival Tuberculin Tests.—Dr. E. R. BALDWIN, of Saranac Lake, N. Y., said that he had sent a supply of tuberculin to forty clinicians and sanatorium physicians, with directions for a uniform method of testing and recording the results. Two solutions of 0.33 per cent. and 0.5 per cent. respectively of dried and purified old tuberculin were issued, accompanied by an eye dropper graduated to 0.25 cc. Eye disease of any kind was considered a contraindication to the employment of the test, and repetition in the opposite eye was advised with the stronger solution, in case the weaker solution failed to cause reaction. The test was tried on 887 persons. In 190 a second instillation was made in the opposite eye, and in ten a second instillation was made in the same eye. Seventy per cent. of the known tuberculous

cases gave a positive reaction; 35.9 per cent. of the suspected cases gave a positive reaction; 14.1 per cent. of patients suffering from some other disease gave a positive reaction; and 18.3 per cent. of supposed healthy individuals reacted. There were twenty-four severe reactions, ten of which persisted beyond five days. In one instance keratitis followed in a scrofulous patient. Eighteen per cent. of the second instillations in the opposite eye produced reactions, and all of those in the same eye. The cutaneous test was subsequently applied in fifty-two, and the subcutaneous in eighty-nine cases, which resulted in a considerable increase in percentage of the positive reactions among the suspected cases. He concluded that the conjunctival tuberculin test, performed with weak solutions, by a single instillation, had some value in confirming the presence of tuberculosis in the early stages. It had little value if tuberculosis was merely suspected. The value in distinguishing "active latent" tuberculosis from healed tuberculosis in apparently healthy persons was not determined. Repetition of the test in the same eye had no advantage over the cutaneous and the subcutaneous tests in the percentage of reactions produced, and it might be misleading and dangerous. Repetition in the other eye could not be recommended. The reaction was unreliable for prognosis. If the test was used with proper precautions the danger to the eye was slight and did not exclude the test when fever was present. It should, however, be used in adults, as the cutaneous test was found equally valuable for children and it (the cutaneous test) was harmless. The cutaneous test by the simultaneous use of dilute and strong tuberculin offered a method of detecting and excluding tuberculous infection, with no danger or inconvenience. Experience was needed, however, to show the value of the method. The subcutaneous test should be restricted to cases in which a focal reaction was desired, and in which the other tests had given negative results.

(To be continued.)

Book Rotices.

Traité de l'alimentation et de la nutrition à l'état normal et pathologique. Par le Dr. E. MAUREL, médecin principal de Reserve de la Marme, professeur à la Faculte de médecine de Toulouse. Deuxieme volume. Les rations à l'état normal. Ration moyenne d'entretien de l'adulte. Ration de croissance et après l'age adulte. Paris: O. Doin, 1908. Pp. xx-666.

The author holds that scientifically we can indicate what are the quantities of each of the substances which compose our organism that we excrete day by day, and consequently what should be contained in our food to repair the loss, or, as Chittenden has it, to maintain the physiological economy of nutrition. The present volume is devoted to a brief survey of the ration in general, and a ration is defined as the total of organic and mineral (food) substances which, under given conditions, correspond to the totality of our needs.

There is broad consideration of the mean ration to maintain the adult man from the standpoints of its organic and its mineral constituents, also of the ration for the adult woman, and the practical application of the data obtained is described.

In a section on the ration during development, the author treats of the food for infants during the first two years, and of that needed from the third

year to adult life.

A final section is devoted to the ration needed after adult age, or after fifty; and this is divided into the periods between fifty and seventy and after seevnty.

The author has aimed to make this work thorough, and it gives a useful and comprehensive survey of diet for the healthy.

Die ärstliche Begutachtung in Invaliden- und Krankenversicherungssachen. Zum praktischen Gebrauch für Aerzte, Krankenkassen und Verwaltungsbehörden. Von Assessor Seelmann, Mitglied und stellv. Vorsitzenden des Vorstandes der Landesversicherungsanstalt Oldenburg. Leipzig: F. C. W. Vogel, 1908. Pp. 64

Mr. Seelmann, vice-president of the State Insurance of Oldenburg, a jurist by profession, has collected his papers on medical opinions in regard to labor insurance, which have appeared in quite a number of medical, dental, social, legal, and other professional journals during the past year. Some of these essays he has enlarged, and now publishes a pamphlet of great interest for the physician, lawyer, expert, and judge in state insurance questions. The booklet is of special value for Germany, as it refers to German labor insurance laws, but insurance men and sociologists of America may also read it with interest.

The Sanitation of Recreation Camps and Parks. By Dr. Harvey B. Bashore, Medical Inspector for the Pennsylvania Department of Health. First Edition: First Thousand. New York: John Wiley & Sons; London: Chapman & Hall, 1908. Pp. xi-109.

The fortunately increasing tendency to spend vacation in camps makes it very desirable for the intending camper to have a practical guide to camp sanitation. In this book advice is given in regard to the situation and construction, the water supply, the disposal of waste, the surroundings of the camp, and the sanitary care of parks. The book is not technical, and should prove a useful companion to all who take up this desirable phase of outdoor life.

Diets in Tuberculosis. Principles and Economics. By Noel Dean Bardswell, M. D., M. R. C. P., F. R. S. (Edin.), Medical Superintendent, King Edward VII Sanatorium, and John Ellis Chapman, M. R. C. S., L. R. C. P., Medical Superintendent, Coppin's Green Sanatorium. London: Henry Frowde (Oxford University Press) and Hodder & Stoughton, 1908. Pp. 184. (Price, \$2.50.)

Pathological research and clinical observation have completely revolutionized our ideas about consumption during the past twenty-five years. The treatment and the results attained in 1907 should be compared with those of 1880. Our therapeutics is no longer confined to such drugs as antimony, digitalis, creosote, or such accessories as blisters, leeches, bloodletting, and plasters; we rely on rest, fresh air, and diet; that is, a carefully regulated life, with freedom from fatigue and worry. The last named

of the three agents, diet, is the theme of the book before us. It contains nothing new, but it offers to the practitioner a very valuable adjuvant, such as is not to be found in any textbook, and the matter is brought forward in the form of a compendium. As a report to the English Royal Society it takes, naturally, only British conditions into consideration, such as the diet of the poorer class, the wage earning capacity of consumptives, the cost of diet at

sanatoria for working classes, etc.

The book is divided into eight chapters, of which Chapter I serves as an introduction and Chapter VIII as the conclusion. Chapters II and III treat of the general principles of construction of diet for consumptives. The comparative economy of various food stuffs is considered in Chapters IV and V, while Chapters VI and VII speak of the forms of special diets. An appendix contains tables which show the forms of diet adapted in other than English sanatoria, reports from English sanatoria,

and an index.

Electrical Treatment. By WILFRED HARRIS, M. D., F. R. C. P., Physician to Out Patients, Physician to the Department for Nervous Diseases, and Lecturer on Neurology, St. Mary's Hospital, etc. Illustrated. Chicago: W. T. Keener & Co., 1908. Pp. x-383.

It has been the author's purpose to present a broad view of the various forms of electrical treatment as practised to-day, giving particular attention to what may be done in medical practice with a good faradic and galvanic battery. He describes the apparatus and methods, the faradic current and its use in treatment, the galvanic current and galvanism, electric baths, the sinusoidal current and its medical applications, x rays, static electricity, and the high frequency current. As far as possible the theory of the various forms of current is explained, and the text is well illustrated. The book is one of the best handbooks on this subject that have been

Scientific Nutrition Simplified. A Condensed Statement and Explanation for Everybody of the Discoveries of Chittenden, Fletcher, and Others. By Goodwin Brown, A. M. New York: Frederick A. Stokes Company, 1908.

The author has sought to present in condensed form and untechnical language the principles of nutrition advanced by Mr. Horace Fletcher, Professor R. H. Chittenden, and Professor Irving Fisher. Personal experience prompted him to study the writings of these well known authors, and the application of their methods resulted in such physical betterment that he has summarized their work in this little volume, which he hopes will benefit those men and women who, while in the prime of life, are the victims of their own dietary indiscretions. He has accomplished his purpose of presenting his facts in a readable form for laymen, and the book should prove to be quite useful to many persons.

Miscellany.

The Antituberculosis Crusade at the County Fairs.—"Every thirty-six minutes there is a death from consumption in the State of New York," so read several charts of the tuberculosis exhibitions of the State Charities Aid Association, which are to be shown at thirty-six of the county fairs of this State during the coming fall. To many this is a bit of news, at once surprising and startling. The great majority of people have no conception of the awful ravages of this disease, of the sorrow, suffering, misery, destitution and squalor that are left in the trail of the "great white plague"; more profound still is the ignorance of the nature of the disease. Believing and regarding it as hereditary and incurable, humanity has from time immemorial suffered tuberculosis to rage unchecked, but now however. thanks to science, it has been known for some twenty years that this plague is not only not hereditary, but that it is curable in the early stages, and most important of all, that it is preventable perhaps more so than any other germ disease. To disseminate our present day knowledge of the means and methods for checking and securing a control over this scourge, an educational campaign was carried on in nine cities of New York State, during the past year. But the people living in the country should get the message also; to them should be imparted our information about the disease, for though it is not generally known that in the small towns and rural districts of this State tuberculosis is almost as prevalent in proportion to the population as it is in the large cities. still such is the case, however, as has been deter

mined from an examination of the vital statistics of all the towns and villages of the State. The county fairs offer a splendid opportunity of reaching the people of the rural districts, and of bringing home to them the essential facts about this disease, its nature, its extent, how it spreads, how it may be cured and prevented. Over 400,000 people, it is expected, will hear the gospel of the antituberculosis crusade. Each exhibit will be made up of maps. charts, diagrams, models of well lighted and ventilated factories, together with models of sweat shop workrooms, and dark, poorly ventilated bedrooms where the consumption germ finds an excellent breeding place. Pictures of dispensaries, hospitals, and sanatoria where consumptives are treated, radiographs and photographs of healthy and diseased lungs will be shown. Scores of short, terse, pointed texts will be displayed about the exhibits. Nothing gruesome or objectionable has been allowed to creep into the exhibits, so no one need stay away on that account. The tone throughout is optimistic, for it has been felt that in a great tremendous campaign like this, the greatest perhaps that ever has or ever will be carried on by preventive medicine, optimism is a prime requisite.—Bulletin of the State Charities Aid Association.

Public Health and Marine Hospital Service:

List of changes of stations and duties of commissioned and other officers of the United States Public Health and Marine Hospital Service for the seven days ending September 30, 1908:

BOYD, FRANK, Acting Assistant Surgeon. Granted four days' leave of absence from September 22, 1908.

EBERT, H. G., Passed Assistant Surgeon. Relieved from duty at San Francisco and directed to proceed to Manila, P. I.

FOSTER, J. P. C., Acting Assistant Surgeon. Granted ten days' leave of absence from September 23, 1908.

GASSAWAY, J. M., Surgeon. Granted one day's leave of absence.

absence.
GCLDSSOROUGH, B. W., Acting Assistant Surgeon. Granted two days' leave of absence from September 29, 1908.
GRAHAM, K. H., Pharmacist. Directed to proceed to Baltimore, Md., for temporary duty.
LYALL, R., Acting Assistant Surgeon. Granted an extension of seven days' leave of absence from September

28, 1908, without pay.
MATHEWSON, H. S., Passed Assistant Surgeon. Granted

one day's leave of absence.

MEAD, F. W., Surgeon. Leave for one month, granted August 7, 1908, amended to read twenty-seven days from August 26, 1908.

MULLAN, E. H., Assistant Surgeon. Relieved from duty at Ellis Island, N. Y., and directed to proceed to Mon-

treal, Canada.

SALMON, T. W., Passed Assistant Surgeon. Directed to proceed to Stapleton, N. Y., upon temporary duty.

SAFFORD, M. V., Acting Assistant Surgeon. Granted four days' leave of absence from September 24, 1908, under paragraph 210, Service Regulations. SCHERESCHEWSKY, J. W., Passed Assistant Surgeon. Di-

rected to proceed to the Bureau upon special temporary duty.

STEARNS, H. H., Acting Assistant Surgeon. Granted four days' extension of leave of absence from September 14, 1908, on account of sickness.

STERNS, C. O., Pharmacist. Assigned to station, Hygienic Laboratory, Washington, D. C. Troxler, R. F., Pharmacist. Assigned to station at Evans-

TROXLER, R. F., Pharmacist. Granted seven days' leave of absence from September 28, 1908.

Appointment.

Dr., S. A. Ransom appointed an acting assistant surgeon for duty at Shanghai, China.

Board Convened.

A board of medical officers convened to meet at Seattle, Wash, for the purpose of examination of two Chinamen from Steamship Kuncric. Passed Assistant Surgeon M. W. Glover, chairman; Assistant Surgeon C. W. Chapin; Acting Assistant Surgeon F. R. Underwood, recorder.

Navy Intelligence:

ALLEN, D. G., Assistant Surgeon. Detached from duty at the Naval Medical School, Washington, D. C., and or-dered to a course of instruction at that school on October 1, 1908.

BOLAND, M., Assistant Surgeon. Detached from the naval recruiting station, Detroit, Mich., and ordered to the

Castine, when commissioned.

Brown, E. W., Assistant Surgeon. Detached from the Naval Hospital, Norfolk, Va., and granted three months' sick leave.

HARLAN, T., Acting Assistant Surgeon. Ordered to a course of instruction at the Naval Medical School,

Washington, D. C., October I, 1908.

Johnson, L. W., Assistant Surgeon. Ordered to a course of instruction at the Naval Medical School, Washing-

of instruction at the Naval Medical School, Washington, D. C., October I, 1908.

Porter, F. E., Passed Assistant Surgeon. Detached from the Navy Yard, Washington, D. C., and ordered to the naval recruiting station, Detroit, Mich.

Schmidt, L. M., Assistant Surgeon. Detached from duty at the Naval Hospital, Annapolis, Md., and ordered to a course of instruction at the Naval Medical School, Washington, D. C. October I, 1008.

Washington, D. C., October 1, 1908.
Shippen, L. P., Assistant Surgeon. Ordered to a course of instruction at the Naval Medical School, Washing-

ton, D. C., on October 1, 1998.

Stanley, A. C., Assistant Surgeon. Detached from duty at the Naval Medical School Hospital, Washington. D. C., and ordered to a course of instruction at the

TURNER, H. W. B., Assistant Surgeon. Detached from duty at the Naval Medical School Hospital, Washington, D. C., and ordered to a course of instruction at the school.

Army Intelligence:

Official list of changes in the stations and duties of officers in the medical corps of the United States Army for the week ending October 3, 1908:

CARTER, W. F., Major, Medical Corps. Retired from active service upon his own application, to take effect July 8, 1000, when he shall have completed thirty years

COBURN, H. C., First Lieutenant, Medical Reserve Corps. Placed on active duty; will proceed to Washington, D. C., and report on October I, 1908, for a course of instruction at the Army Medical School.

EBER, A. H., First Lieutenant, Medical Reserve Corps. Ordered from Fort De Soto, Fla., to Key West Barracks,

Fla., for temperary duty.

JOHNSON, C. W., First Lieutenant, Medical Reserve Corps.

Ordered with troops from Fort Des Moines, Ia., to
tournament at Louisville, Ky.

KEARNY, R. A., First Lieutenant, Medical Reserve Corps.
Placed on active duty; will proceed to Washington,
D. C., and report October 1, 1908, for a course of instruction at the Army Medical School.

KNOX, H. A., First Lieutenant, Medical Reserve Corps.
Assigned to active duty; ordered to Fort Michie,
N. Y. for duty.

N. Y., for duty. lieved from duty with Company C. Hospital Corps, at the Army General Hospital, Washington, D. C., and PHILLIPS, H. F., First Lieutenant, Medical Reserve Corps. Placed on active duty; will proceed to Washington, D. C., and report on October 1, 1908, for a course of instruction at the Army Medical School.

SLATER, E. F., First Lieutenant, Medical Reserve Corps. Ordered from Madison Barracks, N. Y., to Plattsburg Barracks, N. Y., for temporary duty.

STARK, A. N., Major, Medical Corps. Granted leave of absence for one mouth to take effect about December.

absence for one month, to take effect about December 15th, with permission to apply for an extension of fif-

teen days.

Tyler, G. T., First Lieutenant, Medical Reserve Corps.

Ordered from Fort Porter, N. Y., to Fort Jay, N. Y.,

Wells, F. M., First Lieutenant, Medical Reserve Corps. Ordered from Fort Robinson, Neb., to St. Joseph, Mo., for duty with the United States troops.
WOLFE, E. P., Captain, Medical Corps. Granted leave of

Births, Marriages, and Beaths.

FUNKE—McCaulley.—In Philadelphia, on Wednesday,
September 23d, Dr. Alfred H. Funke and Miss Elizabeth M. McCaulley.

JENNINGS-JUDSON.—In New York, on Wednesday, September 30th, Dr. Walter D. Jennings and Miss Mabel

ROSENBAUM—BELBER.—In Philadelphia, on Tuesday, September 22d, Dr. George Rosenbaum and Miss Rebecca

SUTTON—CUMMINGS.—In River Forest, Illinois, on Friday, September 18th, Dr. Howard Anderson Sutton, of Philadelphia, and Miss Julia Stewart Cummings.

WFED—HOWELL.—In Plattsburg, New York, on Saturday, September 19th, Dr. Frank W. Weed, United States Army, and Miss Abigail S. Howell.

BARTSCHER.-In St. Louis, Missouri, on Monday, Septem-BARTSCHER—III 5t. LOUIS, MISSOURI, OH MORREY, SEP-ber 28th, Dr. Hugo W. Bartscher, aged forty-nine years. CLARK.—In Portland, Maine, on Thursday, September 24th, Dr. Walter T. Clark, of Worcester, Massachusetts. FISHER.—In Providence, Rhode Island, on Wednesday,

September 30th, Dr. George Russell Fisher, aged fifty-five

years.
Grosser.—In Wilkesbarre, Pennsylvania, on Thursday,
September 24th, Dr. Claude R. Grosser.
KINNEAR.—In Clifton Springs, New York, on Tuesday,
September 29th, Dr. Beverley Ö. Kinnear, aged sixty years.
Phillips.—In Cape May, New Jersey, on Sunday, September 20th, Dr. Edward H. Phillips, aged seventy-eight

SENNER.—In New York, on Monday, September 28th, Dr. Joseph H. Senner, aged sixty-two years.
SHILAND.—In Watervliet, New York, on Thursday, September 24th, Dr. John Cramer Shiland, aged fifty-three

Sewell.—In Cave Springs, Georgia, on Sunday, September 27th, Dr. Isaac Sewell, aged thirty-three years. Summers.—In Atlantic City, New Jersey, on Thursday, October 1st, Brigadier General J. E. Summers, Medical Corps of the United States Army, retired. TAYLOR.—In Defiance, Ohio, on Saturday, September 19th, Dr. Dwight B. Taylor.

Winters. In Jesington, Rentacky, on Tuesday, September 29th, Dr. John W. Whitney, aged seventy-nine

ORATION ON SURGERY.

Some of the Achievements of Modern Surgery.*

By Frank LeMoyne Hupp, A. M., M. D., Wheeling, W. Va.,

Attending Surgeon to the City Hospital.

It is altogether fitting and proper that we should gather together here in the capital city of Harrison County to pay the homage of our profound gratitude and admiration to the fathers of American surgery, and to discuss and interchange ideas with regard to the laboratory and clinical research work, which has been accomplished with such signal success within the past few years.

Many years ago it was the writer's inestimable

privilege to receive his first lesson in surgery at the operating table in the old building of the North Wheeling Hospital. The man holding the knife was that pioneer teacher and fearless operator, Dr. Washington L. Atlee, of Philadelphia. physicians who witnessed the work of that April morning in 1877 were Dr. John Frissell, Dr. E. A. Hildreth, 1st, Dr. Robert W. Hazlett, Dr. C. A. Wingerter, Dr. M. F. Hullihen, Dr. S. L. Jepson, Dr. Archibald S. Todd, and Dr. John C. Hupp, all of Wheeling, and Dr. John Todd, of Bridgeport, Ohio. There were two cases prepared to receive whatever benefit could be derived from one of the greatest craftsmen in American surgery. The operative procedures were, one for the removal of a multilocular ovarian cyst, and the second was for the evacuation of a collection of pus in the right lower quadrant of the abdomen, probably appendical or tubal in origin. Aside from a very ordinary washing of the hands, and the wearing of protecting aprons of unsterile muslin and rubber, no other preparation was made, and no pretense at antiseptic methods attempted. The second of those two patients is alive and in health to-day, with a perfectly firm abdominal

wealth.

That great teacher, and those associated with him on that memorable day, with two exceptions, have gone to their reward.

cicatrix, living beneath the shadow of our City Hos-

pital. These were among the first abdominal sec-

tions performed within the borders of our common-

The scholarly contributions from the pen of Dr. Atlee, teeming with seductive argument, eloquent appeal, and powerful rhetoric, coming as they did from the frontier line, and his courageous work in

*Read at the annual meeting of the West Virginia State Medic. Association, Clarksharg, May 12, 1908.

the face of the most trenchant criticism, while little spoken of in the history of surgery, not only developed the character of coming generations of medical men, but acted as a safe and sane guide to the estimation of the scientific spirit, which inspired their practice. It required the valor and resolution of a knight to declare one's convictions, and an equal amount of courage to execute an innovation in those formative days. For there were occasions in Atlee's earlier work, true also in the history of that pioneer Kentuckian, Ephraim McDowell, when the exploitation of any new and radical idea was met and retarded by the fiercest public opposition.

It is reported (1) that the classical ovariotomy performed by McDowell, in 1800, created so much bitter criticism, both professional and public, that a mob collected around the house in which it was performed, prepared to attack the surgeon if he failed. While much later Atlee's life was more than once threatened because of a fatality following an abdominal section. Before the time when Atlee visited Wheeling and subsequently, some of us were privileged to witness the work of that leader of the vanguard in affairs surgical, here in our mountain State, Dr. John Frissell, whose masterly work in all branches of surgery, stood as a beacon light, encouraging others of the present generation on to better and more difficult achievements, and search lighting the pathway into broader fields. His was a large heart, a steady hand, and a well poised mind.

How alluring it would be to turn the yellow pages of the forgotten past back through the developmental era of American surgery, where stand forth in bold type the names of John Jones, Warren, Bige-low, Atlee, Gross, Agnew, Willard Parker, Marion Sims, Sands, and Markoe, and a host of others; to review a history of that formative era of our own Western Virginia, where the patience, zeal, and skill of a Hullihen or a Frissell are set forth. How interesting and profitable a record of their methods and end results would be to the members of this West Virginia Society. While it is altogether fitting and proper that we should give a full measure of devotion to the spirit of the men of vesterday, it is rather for us to honor and encourage that scholarly body of present day workers, who in the laboratories of experimental research, through merciful vivisection, are making possible the most interesting clinical advances, and who have made and are making medicine the link that unites science with philanthrophy.

The world shows too little appreciation for that spirit of devotion to a high purpose along medical and scientific lines, a devotion which sinks the selfish in the common weal. Witness the lives of a Lazear

or a Walter Reed, and a host of others of our craft. Men who lived and died for a cause, fired by a love of knowledge; men who sacrificed their very life's blood on the altar of science and humanity; men who laid up few treasures beyond a meagre blessing of their brother men, and no investments save that which adds to the sum of human knowledge and experience.

To review and do full justice to a subject so progressive and changeful as the practice of surgery, as we see it to-day, to involve ourselves in the discussion of the achievements of the world's operators, the living men, would require a great deal of time, and very many volumes. Only a few, therefore, of the more important advancements will be

touched upon.

ANÆSTHESIA.—Somewhere in the Genesis of the Holy Writ we find: "And the Lord God caused a deep sleep to fall upon Adam and he slept; and He took one of his ribs and closed up the flesh instead thereof." This is probably the very first record of painless surgery. There is no theme in the whole realm of medical thought, no chapter in the history of surgery so interesting; from the God given sleep for the first man; the carotid pressure of the Assyrians; the administering of the paralyzing hemp, antimony, and curare of the Chinese; the mandrake of the Greeks and Romans: down over the blazed trail of our forefathers, leading to the advent of ether and chloroform.

How many persons, who by necessity have subjected themselves to the surgeon's knife, have paused to reflect over the poignancy of their agony had no anæsthetic been used? If a surgical operation is a matter of serious dread now, how much greater must it have been when the patient, strapped to the table, was alive to every stroke of the cold

The overwhelming desire on the part of the profession to annihilate pain during surgical procedure brought the names of three men, with their discoveries, into everlasting remembrance, within three short years. Horace Wells with his nitrous oxide gas, in 1844; Morton with ether in 1846; and Simpson bringing chloroform in 1847.

These discoveries, together with the creative genius of Lord Lister, a few years later on, "swept away the long established metes and bounds of the field of operative surgery, and made it as limitless as are the diseases and injuries of the human body and man's desire and efforts to relieve them." (Stephen

At the City Hospital, in Wheeling we use ether almost exclusively when a general anæsthetic is required. The continuous drop method is employed, and it is preceded one half hour by the hypodermic administration of morphine and atropine. Our experience, covering twenty years, justifies the hearty endorsement of Murphy's words (2) that "chloroform is rarely justifiable; that the use of scopolamine from present statistics is quasicriminal. anæsthesia has a permanent place in selected cases. Nitrous oxide has its position for short anæsthesias; its use before ether is unnecesary and complicating. Ethyl chloride is a fairly safe anæsthetic in appropriate cases.

Accidents Due to Anæsthesia.—Dr. Mitchell (3)

thinks that if all instances of death directly due to the anæsthetic were known the rate would be much higher than that ordinarily given, that is: I in 1,000 for chloroform, I in 10,000 for ether, and I in 100,-

ooo for nitrous oxide gas.

Dr. Bevan (4) after extolling the merits of nitrous oxide, places the mortality at I in 2,000 for chloroform, I in 5,000 for ether, and I in 50,000 for nitrous oxide gas. Henle (5) reports 1,787 abdominal operations followed by 143 cases of pneumonia, with a mortality of sixty-five per cent.; Czerney, 1,302, with fifty-two cases of lung complications; Kümmell, of Hamburg, 1,754 laparotomies, with forty-three cases; Kausch (Mickulicz's clinic), 1,881, with forty-five cases of lung complications.

La Pointe (6) collects thirty-three cases from the literature, not including two of his own, of death due to enlarged thymus gland, following soon after

the beginning of the anæsthesia.

Local Anæsthesia.—With Halsted and Corning (1884-5) its early exponents, and later with Reclus and Schleich overcoming the prejudices brought about by the indiscriminate infiltration of large doses of cocaine, this method of annihilating pain

has undoubtedly come to stay.

The last year or two have witnessed marked improvements in the technique of local anæsthesia; important among these are the injection of nerve trunks and the addition of adrenalin to the solutions used. Dr. Mitchell uses a one per cent. solution of cocaine for the nerve blocking, as suggested by Crile, and one tenth of one per cent. solution for ordinary infiltration. During a period of the first three months of 1907, Mitchell executed over forty per cent. of all his operations under local anæsthesia, including amputation of the limbs, wiring of fractures, resection of glands of the neck, inguinal hernia, rib excision, trephining, thyreoidectomy, breast excision, and many abdominal operations.

BIER'S TREATMENT .- With his gift, the Stanungs (obstructive) Hyperamia, to the profession, published first in 1892, August Bier (7), late professor of surgery in the University of Bonn and recently elevated to the chair of surgery in the University of Berlin, has certainly bound up the broken reeds and cheered the struggling hearts of many who suffer. His discovery, with its manifold benefits to humanity, placing as it does within the reach of the surgeon a weapon of no mean power, creates beyond dispute a distinct epoch in the field of surgical endeavor.

Verily, from the light of new discoveries blazing about us, we are well nigh blinded by their near and sudden glory. Some distant objects that we once saw distinctly, and which seemed permanent in their usefulness, have altogether faded or have grown so dim and shadowy that in "the strife of aching vision" we scarcely know what they are, or where

they are.

Hear then, how the ingenuity of the Berlin savant has revolutionized our ideas.

1. Bier's treatment (8) increases, artificially, redness, swelling, and heat; three of the cardinal symptoms of inflammation, the very factors we have always sought to avert.

2. He asserts through the use of the ice bag and

of a phlegmon or a lymphangeitis, that the defending power of the leucocyte is compromised, and the bacteria assisted in their work of destruction. Thus two time trusted measures are pushed aside.

3. Increased temperature, or hyperæmia, Bier

considers a part of the healing process.

4. He maintains that the tuberculous joint must be movable after the disease is healed; that a stiff joint following the repair of a tuberculous arthritis should not be considered a good result. That the immobilization in these joints is contraindicated. That the resection of a tuberculous joint may rid the patient of the focus of mischief, but should be considered to-day a mutilation.

5. That tubing and wicks which were used yesterday to drain the abscess cavities are to-day considered by Professor Bier as relics of barbarism, unnecessary and even harmful. The cupping glass in conjunction with the *Stauungsbinde* is sufficient to empty the cavity and promote the healing.

"I believe," writes Professor Bier (9), "that the practical use of hyperæmia represents the most general and comprehensive mode of treatment in medicine; for I do not know of another remedy that could be successfully employed in so many directions. I have described such a variety of different troubles that were subjected to hyperæmia that many may think I have gone too far. But, on the contrary, I am convinced that this remedy, used by Nature in such a profuse measure to combat all sorts of lesions, is destined to be far more extensively used than has hitherto been attempted." John B. Murphy writes editorially (10) that a very extensive use of the Bier's treatment has convinced him that its efficacy is underestimated; that it is indifferently applied; that it is even of greater service in the acute than in the chronic infective processes; that it is curative in rodent ulcers of the face; that it is palliative in inoperable carcinoma to which it can be applied. Surgeons in general report, that better results are being obtained, and a wider field of usefulness developed, as they become more familiar with the method and more skilled in its use. It is not a "cure all" or a fad for the specialist, but a rational treatment based upon sound principles, and can be used by every practitioner in his daily work.

It is interesting to note that the idea of making use of an increased volume of blood in and around the diseased focus (Willy Meyer, II) was conceived by Bier during his studies of the observation of the late Professor von Rokitansky, who found that patients who had suffered from stasis in the pulmonary circulation, due to heart disease, never exhibited an active lung affection on post mortem

examination.

Action Explained.—Hollister (12) alleges that the treatment avails, not so much because of the hyperleucocytosis, as because of the hyperopsonization, and the necessity of combining passive hyperæmia with surgery depends on the fact that the local opsonic power is increased. He advises raising the general opsonic index by means of appropriate vaccines if necessary.

Another writer (13) explains the action of this treatment as due to the transudation of serum that occurs into the diseased area, physically diluting the toxines and thereby reducing the intensity of their

action. This dilution also serves to facilitate the gradual absorption and consequent excretion of these noxious materials. The antibodies also take a hand in diminishing the virulence of the toxines. The migration of leucocytes invariably favors phagocytosis. In addition, the leucocytes, it is stated, form a membrane, thus walling off the disease area, limiting its spread by continuity, and depriving the bacteria of new culture media.

Technique.—1. The bandage used is the broad Esmarch, one layer to overlap the other. (Willy

Meyer.)

2. The pulsation of the artery must always be felt while the bandage is in position.

3. A red warm hyperæmia, not a blue or cyanotic one, is desirable. (Schmieden.)

4. Pain is always to be relieved not increased by the treatment.

DIRECT TRANSFUSION OF BLOOD.—A recent writer has this to say of the direct transfusion of blood (14): "Rarely, if ever, will there be enough advantage in the use of blood transfusion, to overbalance its greater dangers and difficulties, and the greater delay in administering it." The experimental research of Crile (15, 16, 17) developing the technique of this line of endeavor, controverts emphatically the foregoing. Crile's paper before the section in anatomy and surgery, at the last meeting of the American Medical Association, detailed the most brilliant work along this line. In his clinical transfusions he utilized the radial artery of the donor, and the proximal end of any superficial vein of the arm of the recipient. Thus the vascular systems of two individuals may be united so that intima comes in contact with intima; that blood may be transferred without clotting; that the operation may be done painlessly; that the blood lost by the donor is regained in from four to five days. The technique insures a perfect control of the amount transferred, an important point, as overcharging the pulmonary circulation is dangerous.

The anastomosis is a temporary one and is effected by means of a metallic tube over which a cuff of the artery is turned back, exposing intima. The vein being drawn over this and sutured into place.

(Mitchell.

The enthusiasm exhibited by those who had listened with bewilderment to the restoration of Crile's exsanguinated patient will not be soon forgotten. The man had practically bled to death, and bore the stamp of the hippocratic countenance—cold, unconscious, and livid. Two brothers had come to the rescue and emptied their life's blood through the tiny metallic cannula into their all but dead kinsman. The scene, a most dramatic one, was described: The pulsating radials returned stronger and stronger; the pallid lips became a normal red; the warmth of a brother's blood relieved the death like chill, the eyes opened wide, and the patient expressed his gratitude feelingly to those about him.

The occurrence of spontaneous cessation of hæmorrhage in two of Crile's cases.—each of which was pathological,—suggests strongly this method of treatment for cholæmic, hæmophilic, and other forms of pathological hæmorrhage. Since the healthy blood of one individual is apparently physiologically interchangeable with that of another, if the

blood lost by one is replaced by an equal quantity from another, hæmorrhage may by direct transfu-

sion be eliminated. (Murphy, 1907.)

Here we have the twentieth century technique of a master stroke, practised in the middle ages, mentioned by Savonarola, forgotten by the nineteenth century, and revived by Cleveland's wizard surgeon, a priceless boon to man.

APPENDICITIS.—A helpful recent contribution to appendical surgery is from the pen of Dr. Stanton, of Schenectady. His observations are based upon the operative findings in 1,019 cases, and studied with reference to the pathological course in this disease. He ascribes the uniformity of pathological findings in those cases not immediately operated on, to the fact, that every effort was made to limit the further spread of the infection through peristalsis, by the Ochsnerian treatment of rest and starvation. In 191 acute cases subjected to this treatment, there were but three deaths or 1.57 per cent.

Stanton believes that there can be no doubt of the advisability of early operative interference prior to the advent of the overwhelming peritoneal infection; before the exudate becomes seropurulent in

character.

We cannot help recognizing the wisdom of Dr. Ochsner's teaching, as voiced by Dr. Stanton, in certain acute cases of appendicitis, who in the country districts are so far removed from the surgeon. And we believe and here wish to emphasize, that the country practitioner who is not doing major surgery, should be familiar with every detail of the treatment which has been given to the profession by Dr. Ochsner.

Yet, those of us who live in the more populous districts and who see many of these patients know how utterly impossible it is to establish a line of demarcation between the pathological changes oc-

curring within the peritoneal cavity.

Who can determine when the serous exudate becomes purulent, or when the engorged mucosa becomes gangrenous? Often the earlier symptoms give no clue to the real extent of the damage which the appendix has sustained, or of the imminence of diffused and general peritoneal infection (Pilcher). Because of this uncertainty, and because 5,500 cases of appendicitis perish annually in this fair land of ours, we wish to emphasize that in every case of incipient inflammatory trouble resident in the subdiaphragmatic region, the physician and surgeon should act conjointly. There seems to be no reason why cases of appendicitis diagnosticated, and referred to a competent surgeon within twenty-four to forty-eight hours, should not present a mortality of less than two per cent. (Coffee).

John B. Murphy says the man who is having more than three or four deaths in one hundred operations for appendicitis, is either receiving his patronage from incompetent or procrastinating medical men, or he is doing too much manipulating in the peritoneal cavity, under unfavorable condi-

Let this society then, express itself as favoring, with reference to appendicitis: Early recognition, no therapeutics, early and clean surgery, and a perfected technique

Stouther Surgion. It is not within the scope of

this paper to discuss the surgery of the subdiaphragmatic region; two subjects only will be touched upon, gastric ulcer and carcinoma.

Ulcer of the Stomach.—The surgeon and internist agree that operative interference should be resorted to when persistent and thorough internal treatment of gastric ulcer have effected only temporary improvement, and the patient's life has been rendered burdensome through pain, vomiting, and dyspepsia (Stedman, 18). Early diagnosis and prompt surgical relief of acute ulceration should be imperative, when we reflect that perforation, hæmorrhage, and obstruction due to resulting cica-

trices, all contribute to a high mortality.

Ulcers appearing in the young and generally anæmic women, we are told by Foote (19) yield to rational medical treatment in about eighty per cent. of the cases. The remaining twenty per cent. of medical failures are turned over to the surgeon, as a last resort, and he is able to cure about fifty per cent. of them. If the patient shows no improvement in thirty days under medical treatment he never will show it. It is in these patients that surgery has its most brilliant results, in the operation of gastroenterostomy, establishing as it does better drainage of the stomach, and at a point where the food and acidity will not have to pass over the lesion.

The unanswered questions, according to Murphy, concerning the treatment of gastric ulcer are many: "Whether it shall be excision in the greater percentage of cases, gastroenterostomy, or pyloroplasty, with or without pyloric occlusion, is a matter awaiting the final results, in the large number of cases now being treated by these various methods."

Franz Toreck (20) states that sixty per cent. of the cases of cancer of the stomach arise from a concinual acid irrigation of a one time benign ulcer.

A Tribute to the Mayos.—The writer wishes to emphasize the value of the contributions from the pen of W. J. Mayo, to both stomach and intestinal surgery during the past few years. Dr. Mayo's Mütter lecture (34) setting forth the principles underlying the surgery of the stomach; his scholarly essay relating to the recognition of the mesocolic band in gastroenterostomy (35) and the publication of his operating room results, in order to a better understanding of gastric and duodenal ulcer (36), are all classics of the highest order, and should be thoughtfully studied by every internist as well as by him who contemplates the practice of this branch of surgery

That a populous community is not indispensable for the development of the best and the highest, the little town of Rochester, Minnesota, has most

brilliantly demonstrated (Richardson).

Gastric Cancer.—This disease is of much more frequent occurrence than one would suppose. Dowd (21) discloses the startling fact that the census report for 1900 indicates that there were nine thousand deaths from cancer of the stomach in that year.

Professor W. Gilman Thompson, of the Cornell raculty of medicine, in a paper (22) read before the Cleveland Academy of Medicine in February, 1907, makes an eloquent appeal for the earlier recognition of this disease. He summarizes as follows the conditions which combine to make operation, not only justifiable but desirable:

"I. The patient's age should be within the average cancer developing period, for gastric cases, i. e.,

between forty and sixty-five years.

"2. There should be a rapid and decided loss of weight and strength, without other assignable cause, such as chronic gastric catarrh, neurasthenia, mental strain or worry, or chronic general disease, such as diabetes, etc.

"3. There should be evidence of some degree of

stagnation of food contents in the stomach.

"4. There should be failure to improve in marked degree under treatment, after a few weeks' trial. With these four conditions fulfilled, exploration should be seriously considered, despite the absence of gastric pain or other marked gastric symptoms. In addition there may be:

"5. A leucocytosis of 12,000 to 16,000 with polynucleosis and a moderate secondary anæmia, with

low color index.

"6. Decided dilatation of the stomach. With these two additional factors, operation is distinctly indicated. Still further there may be:

"7. Occasional attacks of vomiting, often without

definite relation to food ingestion.

"8. Occult or visible blood in the vomitus or

stools.

"9. Epigastric or right hypogastric rigidity and tenderness on deep pressure. With these symptoms added, the diagnosis can admit of practically no question. In this order of relative importance of symptoms I have purposely left until the last, as being often unreliable, (10) the demonstration of hyperacidity or anacidity, and (11) the so called carcinomatous cachexia, which, while plain enough toward the fatal ending, is often wanting as an early definite appearance."

Mayo has so perfected the technique of this branch of surgery that his recent statistics for partial gastrectomy shows that in eighty-one operations the mortality was fourteen per cent., but in the last twenty-five cases it was only four per cent., and one fourth of the patients were still living three years

subsequent to the operation (Murphy)

Vassalo (23) reports the successful removal of the entire stomach for cancer, the operation lasting only thirty-eight minutes. Four months later the patient was examined and found to be in excellent health and experienced no pain or difficulty in digestion. This brilliant South American operator has performed seventeen pylorectomies with only one death.

In regard to carcinomatous affections of the subdiaphragmatic organs it is interesting to note that Lecene has according to Hartman (24) collected forty cases of primary cancer of the appendix. Recovery seemed complete following operation, four,

three, and two years later.

Trypsin and Amylopsin.—If the trophoblastic theory of Beard and Saleeby, of Edinburgh, and its logical sequence, the trypsin and amylopsin treatment of cancer of the stomach, leads to even a partial conquest of this hitherto incurable malady, the profession will not only be obliged to take these much abused investigators seriously, but the scalpel and needle may be consigned to the corrupting influence of the moth and the rust.

Intestinal Obstruction .- W. J. Mayo (33) points

out that the frequent necessity of resection for the relief of intestinal obstruction is a somber commentary on the diagnostic ability of the profession. In the very large majority of the cases delay is responsible rather than the primary cause of the ileus. The favorable cases are those in which there is interruption of the fæcal current without vascular strangulation.

VACCINE THERAPY AND THE OPSONINS.—Homer B. Smith, of Boston, tells us how the method of defense of an organism against an invading microorganism, was explained by one of Pasteur's successors, Metchnikoff, whose fundamental conception was, that the existence or cultivation of immunity depends upon the digestive action of certain cells of

the body, the phagocytes.

Opsonins are substances normally present in the blood serum, and whose production is stimulated by the injection of sterile emulsions of the dead bacteria whose effect are to be antagonized. The vaccines or bacterins so act on these microscopic enemies of life and health, as to make them more readily the prey of the phagocytic sentinels of the

body.

When Pasteur conceived his preventive treatment for hydrophobia, and our recent distinguished visitor Robert Koch established the practice of injections of bacteria products for curative purposes, and Petruschky and Richardson attempted to hasten the reactions that lead to the healing of the ulcerated Peyer's patch, they foreshadowed the genius of Wright, to whom the world owes an everlasting debt for the placing of this wonderful treatment upon a more definite basis. While some writers are prepared to say that with the use of the vaccines or dead bacteria injections, properly carried out, there can be obtained, not only a marked degree of immunity, but an improvement, both constitutional and local in many subacute and chronic infections, entirely beyond anything previously possible in medicine. On the other hand, Dr. William H. Welch, of Baltimore, has said (25) that "there is no instance of substantial protection from disease, by the injection of killed organisms. It is only by the injection of living cultures that we could expect to get the best results in protective vaccination. The vaccination against smallpox, anthrax, rinderpest, and tuberculosis in cattle is all done by living organisms."

Certainly with undaunted courage, Wright has pushed to the foreground the results of his investigations, so that to-day almost every large hospital, recognizing the importance of the opsonic index in vaccine theraphy as applied to the treatment of various infections, is equipped with the apparatus, material and charts for its practical application.

SURGERY OF BLOODVESSELS.—If there is one department of surgery more than another which has been marked by striking progress, it is the chapter dealing, experimentally and clinically, with bloodvessel suture. That a tube of the delicately thin structure of a vein or an artery can be successfully anastomosed by thread and needle, that a technique has been discovered which makes possible an end to end approximation of these fine spun carriers of the vital fluid, and in so doing, accomplishes that great surgical desideratum, the restoration of tissues as near-

ly as possible to their original position, (Sweet, 26); a technique which consigns to oblivion, compression, cauterization, and the ligature of Ambrose

Paré, seems wonderful to contemplate.

The application of this discovery is broad indeed, comprehending the repair of wounds of vessels, both traumatic and those made by the scalpel; the reestablishment of circulation by suture after complete division of a vein or artery; the surgical obliteration of the aneurysmal sac; the direct transfusion of blood (Crile), and the transplantation of

The infinite possibilities and wide range of usefulness inaugurated through the perfected technique seems little short of miraculous. From the wealth of literature on this subject we have selected one paper which it was our pleasure to hear Dr. J. F. Mitchell, of Washington, D. C., read in February last before the Pittsburg College of Physicians. This paper has not yet appeared in print, but in a personal communication Dr. Mitchell has been good enough to furnish the writer with a copy. He tells us that a complete segment of a vein can be transplanted to take the place of a section of an artery. That complete reversal of the circulation of a limb has been attained by dividing the femoral vein and artery and anastomosing artery to vein and vein to artery. The valves in the veins resist for a time but soon give away. These remarkable possibilities are opened up by the experiments of Carvel and Guthrie at the University of Chicago (27).

The whole thigh has been amputated and replaced; the bone, muscles, vessels and nerves united, and the circulation reestablished after an interruption of one and one fourth hours. Healing of the severed tissues appeared to be as complete as after

an ordinary surgical wound.

The most interesting part of the work, writes Dr. Mitchell, is the transplantation of organs, which may be autoplastic, homoplastic, or heteroplastic. The thyreoid gland, the ovary, testicle, kidney, intestines, heart, and lungs, have all been transplanted together with various other organs. The kidney has been extirpated, washed with salt solution and replaced. Both kidneys of one dog have been removed and the kidneys of another put in their place.

The heart of a small dog was transplanted into the neck of a large one, and its vessels sutured to the vessels of the neck. The circulation was reestablished through the transplanted heart about an hour and fifteen minutes after the cessation of the beat. Strong fibrillar contraction soon occurred. Afterwards contractions of the auricles appeared and, about an hour after the operation, effective contraction of the ventricles began. The transplanted heart beat at the rate of 88 per minute, while the rate of the normal heart beat was 100 per

Scream or, and there . A through and through bullet wound of the heart involving the walls of the left ventricle has been successfully closed by Wilms (28). His incision was made between the fourth and fifth ribs. The pericardium was closed without drainage. This is the same approach as was used by Mikulicz in his intrathoracic work.

In Lenormant's (29) balance sheet of the results

in heart suture, 128 cases are reported with fortyseven recoveries, or 36.7 per cent.

Rehu (30) arrests bleeding from a cardiac wound by compression of the inferior vena cava. He always closes the heart wounds with fine silk, and has collected 124 cases with twenty-four recoveries.

Direct Massage of the Heart in Chloroform Collapse.—Lésas (31) has worked patiently in this field for thirty years. Three routes are described: 1, Osteomuscular flap, called the thoracic; 2, transdiaphragmatic, which entails a careful incision of

the diaphragm; 3, subdiaphragmatic.

This latter route is very simple. After a supraumbilical median laparotomy the heart is subjected to conjoined manipulation, with one hand over the chest and the other in the abdominal cavity, and the heart subjected to rhythmical compression and manipulation. Following the exhibition of this method, six successful cases are reported; two returns of the heart beats for a short time, and two failures.

There seems to be little doubt that we have here a heroic and entirely new method which is able to save life when death is inevitable, and other restora-

tive measures have failed.

SURGERY OF THE LUNGS.—Professor Sauerbruch, of Marburg, Germany, formerly assistant to the lamented Mikulicz, certainly deserves the highest praise for his wonderful achievements in the surgery of the thoracic cavity. His tireless experimental research, seeking to prevent pneumothorax in intrathoracic operative measures, by the use of his ingenious pneumatic cabinet, has opened up a new field for the surgeon, and has demonstrated the ease and safety with which every part of the chest can be entered, through large flaps involving many ribs.

Operations which were hitherto looked upon as impossible can now be performed with every assur-

ance of a successful outcome.

Samuel Robinson, of Boston, (32) has also developed the fact that the thorax may be opened and large portions of the lungs removed under the influence of air pressure, without causing immediate death. His experimental research, included pleurotomias, and pneumectomies (partial or complete), on dogs. Thirty cases in all received operation with nine deaths and twenty-one recoveries. Inflation was effected by means of a positive pressure apparatus of Robinson's creation, and the death rate in this experimental intrathoracic surgical procedure, is much lower than has hitherto been reported,

THE GREAT BLACK PLAGUE.—While every other medical subject has been overshadowed, volumes have been written and millions of money spent in behalf of the preventive treatment of the great white plague. What can be said of the infected sixty per cent. of those 770,000 male Americans, who annually attain maturity, apparently well developed and physically endowed, to propagate a healthful race

of men and women?

Let the present day records of the operating room make answer: Seventy-five to eighty per cent. of the women subjected to abdominal surgery may be directly traced to the ravages of the Neisserian

Let the piteous wail from the parched throats of eighty per cent. of the infantile blind give testimony.

Answer me, are not the five to eighteen per cent. of the entire male population, who act as unwilling hosts to the Spirochæta pallida responsible for the excessive infantile mortality and race suicide, with its baneful consequences?

Thank God, the layman, through the great and good work of a Prince Morrow, a McCormack, and a hundred fearless writers, is gradually but surely being emancipated from the thraldom with which

tradition has fettered him.

The American fathers and mothers with marriageable daughters are now undergoing a schooling at the hands of the medical profession which will result in an adequate realization of the fact that theirs is no divided responsibility in this conflict.

In conclusion we desire to recognize with gratitude and admiration the achievements of a few of our American surgeons along some special lines of endeavor, and to express the profound regret, that the scope of this oration will not permit a full discussion of their work.

Dr. Harvey Cushing, of Baltimore, has focused his studies in the direction of surgical neurology, and as a result of his long and painstaking experimental work, has placed the surgery of the brain and nerves on a high and well balanced level.

Dr. Hugh H. Young, of Johns Hopkins, through his untiring investigation in urological surgery, has stimulated the keenest interest of the profession. His writings, daring operative work, and anatomical demonstrations, especially on the prostate, have

been an inspiration.

Dr. Chevalier Jackson, of Pittsburg, in his devotion to the study of tracheobronchoscopy, œsophagoscopy, and gastroscopy has developed an operative technique along the line of instrumentation, a boldness and dexterity almost startling, that will entitle him to the gratitude and praise of generations unborn. Along the lines of experimental research, the obligation of the entire profession to Dr. Simon Flexner and his faithful collaborators is constantly

increasing. The writer is aware that it is rather presumptuous for one absorbed in the cares and duties of a responsible profession, who has added little to the common storehouse of indigenous science, to have occupied so much of your time. Yet he has been profoundly impressed with the importance of the task, and has endeavored to obey the command which has been laid upon him by this association. He will shelter himself, as Dr. Bigelow would say, under the belief that it may sometimes be permitted even to the drone in the hive, to cause the air to vibrate, in honor and in recognition of the labors of his more efficient colleagues.

He has not attempted to cover the entire field of surgical progress, where there have been made such tremendous forward strides; but has endeavored to lead you to the borderland of a boundless arena, and to point out a few of the more important advances, trusting it may stimulate a profitable discussion.

MIDDLE EAR SUPPURATION.*

By W. Sohier Bryant, A. M., M. D., New York.

Much has been written upon this subject, vet there still seems to be the need for emphazing the necessity of proper and timely treatment, and for stating certain technical points by which serious complications can be avoided, the hearing preserved, and a permanent cure effected. Even if local and systemic extension of the infection of the middle ear has taken place, there are still measures by which fatal consequences may be averted.

The diagnosis of middle ear suppuration is made by inspection of the ear and the discovery of pus coming from the tympanum or from somewhere in the tympanum. Acute cases are sometimes seen before rupture of the drum membrane, consequently no pus is to be found on inspection. In these cases the presence of pus is inferred from a yellowish tinge of the membrane tympani, or by high fever in

Stephen Smith's Into duction to American Practice of Surgery, p. 61.

^{*}Read at the latth Pan American Medical Congress, August, 1408

connection with the acute inflammation of the middle ear. There are a few cases with intact membranes and with no active local manifestation of inflammation where the presence of pus somewhere in the middle ear is suspected from the clinical signs of infection which cannot be accounted for in any other way. There may be pain and tenderness of the mastoid region in these cases, which some time previously have had an active inflammation in the ear. In a few cases with perforation or loss of the tympanic membrane, although pus is not readily found in or about the tympanum, its presence is indicated by local pain and febrile reaction. Careful exploration of the tympanic cavity will usually reveal a small crust, which indicates the seat of infection.

The ætiology of middle ear suppuration comprises a varied bacterial flora which includes all the pyogenic organisms. Streptococci and pneumococci are the usual and the most dangerous varieties. Tuberculous infection is suspected with indolent progressive necrosis. We find that the infecting organism has usually entered the middle ear via the Eustachian tube. In a few cases the infection passes in through an injury of the drum membrane, or by infection of the canal or mastoid region; rarely if ever through the blood current. The cause of the tubal entrance of infections is nearly always some nasopharyngeal disturbance which interferes with the normal tympanic drainage function of the Eustachian tube. The obstruction to drainage also renders the mucosa more liable to invasions through interference with the function of the ciliated epithelium, and by congestion and faulty mucous secretion locally reduces the superficial resistance of the membrane. Interference with the functions of the tuba auditiva is as important an ætiological factor of middle ear suppuration in the exanthematous as in persons otherwise healthy. It is also the chief predisposing factor toward serious extratympanic complications of middle ear suppuration.

Prophylaxis is chiefly directed to putting the nasopharynx in a normal condition and keeping it normal and in preserving the functions of the Eustachian tubes or in restoring these functions if they have been lost. Over ninety-five per cent. of all middle ear suppurations are due primarily to the tubal entrance of bacteria and secondarily to abnormal conditions in the nasopharynx which interfere with the expulsion of bacteria. The nasal douche should be avoided, since it is a common cause of middle ear suppuration. General and local hygiene should be looked to in order that the mucosa may retain its normal bacterial resistance. Resistance to bacteria depends chiefly on the secretion of normal thin mucus. If infection of the tympanum has already occurred, an early section of the membrane is the surest method of preventing later suppuration. For prophylaxis, partial or complete nasopharyngeal obstructions must be removed, the mucous membrane hardened, and normal secretion of thin mucus encouraged.

Complications are usually present in middle ear suppuration. The commonest ones are intratympanic; cholesteatoma; bone caries; granulomata; partial or total loss of the drum membrane and os-

sicular chain. Perforations of the membrane vary in size, position, and number. The position of the perforation indicates the location of the focus of the infection to be attic, Eustachian tube, mastoid antrum, or adjacent tympanic walls. The size of the perforation is indicative of the destructiveness of the process. A multiple perforation is pathognomic of tuberculous infection. Injury to the sound transmitting mechanism is often brought about by adhesions as well as by the loss of structures, and especially by chronic interstitial tympanitis.

The extratympanic complications of middle ear suppuration are very numerous, and are most important from the point of view of fatalities. I. Extensive cholesteatoma eroding the temporal bone and invading the cranial cavity. 2. Extensive caries of the temporal bone with formation of large sequestræ, often including the osseous labyrinth. 3. Mastoiditis or inflammation of the mastoid antrum and cells. 4. Osteomyelitis, or inflammation of the bone and red marrow, usually commencing in the bone of the mastoid process, extending through the temporal bone, and invading the adjacent parietal and occipital bones. 5. Perimastoid cellulitis, inflammation of the tissues covering the mastoid region by direct extension from within. 6. Subperiosteal abscesses occur on the face of the mastoid, and are caused by the pus from within the bone desecting up the periosteum. 7. Mastoid fistulæ, usually multiple, caused by spontaneous drainage of deep lying bone suppuration. 8. Deep cervical cellulitis, caused by escape of pus from the base or inner surface of the mastoid region, and descending down the neck within the deep fossæ. The pus may penetrate into the mediastinum and pleural cavities, thus causing a very serious complication. 9. The tympanic inflammation may attack the labyrinth by invasion of the external semicircular canal, or by penetrating through the fenestræ and causing suppurative labyrinthitis. This is a most dangerous complication, since, besides destroying the auditory and equilibrative functions of the ear, it is very apt to cause leptomeningitis and death. 10. Pachymeningitis is a very common complication of extensive mastoiditis and osteomyelitis. It is not in itself dangerous, but it leads the way for the infection to enter the most vital structures, the pia mater and the sigmoid sinus. 11. Epidural abscess is the result of pachymeningitis; it is a dangerous complication, because of the proximity of the abscess to the arachnoid and sinus. 12. Perisinuous abscess is a complication of an epidural abscess which involves the region of the sinus. This is dangerous because of the threatened extension into the sinus. 13. Sinus phlebitis, one of the most dangerous complications, is due to the extension of the infection into the wall of the lateral sinus, sigmoid sinus, or bulb of the jugular vein. First a parietal thrombus forms over the infected area. This thrombus may increase till it occludes the vessel, and may extend in both directions. It may later break down and be-Sometimes the infection of the come purulent. sinus wall and jugular vein wall extend far beyond an occluding thrombus. In these cases the infected vein or sinus is lined by a mural thrombus. When the virulence of the infection is great and the

resistance of the individual slight, the local toxic effect of the infection may be sufficient to cause necrosis of the meninges at the focus of infection on the dura mater, resulting in gangrene of the meninges and adjacent structures, including the dura mater, sinus, and brain tissue. This condition is usually fatal. 15. Cerebral abscess is an important extratympanic complication of middle ear sup-It may arise from direct extension of the infection through the tegmen and dura, or it may follow the course of the veins and lymphatics and macroscopically have the appearance of a metastatic abscess. The cerebral abscess or abscesses are in the temporal lobe and lie near the tegmen tympani. 16. Cerebellar abscesses usually originate in one of two ways; either by direct extension through the dura mater, in the neighborhood of the sigmoid sinus, or by extension from an infected labyrinth. In the latter case, the infection penetrates through the internal auditory meatus and instead of causing purulent leptomeningitis of the cerebellar fossa, causes an abscess of the adjacent cerebellar lobe. 17. Serous meningitis is an inflammation of the meninges which has not developed into suppuration. Its dangers are compression of the cranial contents and final suppuration. In either case death may result. 18. Purulent leptomeningitis may be due to direct extension from the middle ear, or to a secondary extension from the temporal bone and dura mater. In the middle cranial fossa it usually commences at the tegmen tympani. In the cerebellar fossa it usually commences by extension through the internal auditory meatus or by extension from the neighborhood of the sigmoid sinus. 19. Encephalitis is a diffused infection of the brain tissue; its origin is the same as that of brain abscess, but its course is more acute. 20. Cerebrospinal meningitis is a complication caused by the extension of leptomeningitis or by the extension of the infection into the lateral ventricles and spinal cord. 21. Middle ear suppuration and its complications, especially sinus thrombosis, may give rise to metastatic suppuration in the large joints and pleural cavities and other lymph spaces, also abscess formations in distant cellular tissue and organs. Sinus thrombosis occasionally gives rise to septicpulmonary emboli, which cause pulmonary infection and necrosis. 22. The bacterial poisons absorbed from the infected ear or its complications may be sufficient to cause a fatal septic fever. 23. Bacteriæmia, if the bacteria gain entrance to the blood, may follow suppurative otitis and its complications. Bacteriæmia indicates very low obsonic resistance. and is usually fatal.

Middle ear suppuration and its complications respond to treatment and cicatrize, or occasionally they heal spontaneously. The results in either case are very similar. The natural results are closely akin to operative results, but their course is very slow and fraught with the greatest danger to function and life. Various defects are found after the suppuration is healed. I. Scars of the tympanic membrane, closing perforations made by ulcerative processes. 2. Cicatricial adhesions of the tympanic membrane and ossicles to each other or to the promontorial wall. 3. Perforations and losses of the

tissues of the tympanic membrane which have no tendency to close up. 4. The postaural surface, instead of having the normal convex contour, may be depressed owing to the loss of bone. 5. Permanent postaural fistulæ leading into the tympanum may remain after the process of healing is complete. 6. The ulcerative process in the external meatus may cicatrize and result in a narrow stricture or even total occlusion of the meatus in its osseous portion. 7. Cholesteatomata often form after the cessation of suppuration of the middle ear. These cholesteatomata are a frequent cause of recurrent suppuration and of recurrent mastoiditis. 8. Ulceration may cause the loss of any part or of the whole of the tympanic structures, of the drum membrane, of all the ossicles, as well as of the bony walls. The bony walls usually lost are the annulus tympanicus and posterosuperior canal wall, leaving the mastoid antrum and attic open into the meatus. The canal will then have an enlargement in the inner end. 9. Chronic interstitial otitis, otosclerosis, and rarefying osteitis of the labyrinth capsule are often found after the cessation of suppuration of the middle ear. They are excited by the suppurative inflammation, and the final results are brought about by the diminished blood supply following cicatricial fibrous contraction. Functional defects resulting from middle ear suppuration are deafness, tinnitus, and unstable equilibrium. Deafness and tinnitus are due to pathological changes of the middle ear and cochlea. Disturbed equilibrium is due to injury to the vestibule and semicircular canals, and tension anomalies of the tympanum. The results following convalescence from the extratympanic complications of middle ear suppuration vary with the part affected and the amount of destruction of tissue substances.

Treatment of acute cases requires drainage via the tuba auditiva and through the meatus externus. The first is accomplished by appropriate nasal treatment. The latter is assured by free incision of the tympanic membrane, making a U shaped cut three fourths of the way around the membrane from its upper posterior attachment. After the tympanic drainage is established a cleansing treatment should be employed. If there is much swelling, hot douching every hour with a mild antiseptic solution, such as a saturated solution of boric acid, lessens the swelling and helps the drainage. If there is no swelling, dry cleansing treatment is the best. This consists in wiping out the meatus four times daily and insufflating powdered boric acid. The interval of treatment is gradually increased as the suppuration decreases.

As in acute suppuration, so also in chronic middle ear suppuration drainage is the first point to be looked after. The nasopharynx must be made to allow the tuba auditiva to drain the middle ear. Meatal drainage must also be provided by extensive section of the drum membrane and cicatrices. Next in importance after drainage is the cleansing treatment for the removal of the products of inflammation, pus, epithelium, crusts, etc. Dry wiping is the best means of accomplishing this end, but often the wiping has to be supplemented by intratympanic syringing. Third and last in importance for suc-

cessful treatment are the antiseptic procedures. The best antiseptic is boric acid. Sometimes this has to be assisted for a time by other reagents. Alcohol, hydrogen peroxide, iodoform, pyoctanin, bichloride of mercury, chromic acid, silver nitrate, picric acid, carbolic acid, etc., all have a place in occasional cases. Dry wiping is always preferable to meatal syringing, and should be employed except when there is swelling or extremely abundant discharge. It should be followed by wiping. Perseverance and thoroughness in treatment are sure to be crowned with success. However, it must always be borne in mind that too long persistence in treatment will prolong the discharge when cessation of treatment will arrest the discharge. Allow the ear to heal if it can. Sometimes an acute process is grafted upon a chronic. This combination forms a most dangerous condition, and requires to be carefully guarded against serious complications. The treatment under these circumstances is a judicious combination of the treatment for the acute and chronic middle ear suppuration.

Treatment of intratympanic complications of middle ear suppuration has to deal with: I. Cholesteatoma of the tympanum. A large opening in . the tympanic membrane should be provided, and the cholesteatoma removed by forceps, by wiping, or by intratympanic syringing. After this treatment instillation of alcohol should be continued until serous discharge and desquamations of epithelium have ceased. These patients should be made to report for occasional inspection, because the cholesteatoma is very likely to recur, and if neglected will give rise to extremely serious complications. 2. Intratympanic caries is rarely extensive enough to require more than cleansing treatment for it to heal. If ossicles are dislocated they should be removed. 3. Polypi often recur in the course of middle ear suppuration. They are of little moment except that their size and position may block drainage. If the polypi are very large they can be snared off or morcelled with forceps. If the polypi are small it is wise to leave them in position and treat them by instillation of absolute alcohol till they shrivel up and harden. 4. After the cessation of suppuration, the repair of the sound transmitting mechanism of the middle ear is of great importance for the improvement of hearing and cessation of tinnitus due to middle ear lesions. Closure of the perforations in the drum membrane is a safeguard against future tympanic infection from the meatus. Paper dressings are the best means of stimulating cicatrization of perforations in the drum membrane. Very large perforations may be stimulated to close by touching their edges with trichlor acetic acid or other irritants. When there is a defect in the ossicular chain the loss may be partly compensated for by applying cotton tacks in the neighborhood of the promontory

Treatment of the extratympanic complications of middle ear suppuration for the most part demands capital operations. Space will allow us only to name the treatment of these complications. Extensive cholesteatoma and extensive bone caries and sequestre require some form of mastoid operation for their removal. Mastoiditis, if it has gone past the

congestive stage, requires a complete mastoid operation, which includes the evacuation of every cell and ablation of the mastoid process. Osteomyelitis requires a complete mastoid operation, and, in addition, the removal of all diseased bone wherever it can be found. Perimastoid cellulitis, if the cause is from within, is treated by incision followed by a complete mastoid operation. Subperiosteal abscess requires free incision for evacuation of the pus and a complete mastoid operation. purating sinuses require a complete mastoid operation and removal of the suppurative tracts. Deep cervical cellulitis requires a complete mastoid operation and counter drainage in Suppurative labyrinthitis requires a the neck. Schwartze-Stacke radical mastoid operation and labyrinthotomy. Pachymeningitis, epidural abscess, and perisinuous abscess require a complete mastoid operation and exposure of the diseased dura mater. Sinus phlebitis without thrombosis requires exposure of the diseased dura covering the sinus. If there is thrombosis, incision of the sinus and evacuation of the thrombus is indicated. If the thrombosis extends to the jugular bulb, the jugular vein should be exposed and ligatured well beyond the limits of the phlebitis, and then incised or excised. Gangrene of the meninges and neighboring tissues requires free exposure of the diseased area and wet dressing, preferably with aluminum and lead acetate. Cerebral and cerebellar abscesses require free incision for drainage and sufficient exposure of the dura mater covering them. Serous meningitis with signs of cerebral and cerebellar compression requires a decompression operation, incision of the dura, and drainage of the arachnoid, aided by lumbar puncture if there is cerebellar compression. Purulent leptomeningitis requires complete drainage through extensive incision of the dura mater. Encephalitis requires multiple incision and drainage. Metastatic suppuration and pulmonary emboli require the appropriate treatment for these conditions in addition to the appropriate local treatment for the ear affection. General sepsis is treated by removal of the local cause, by flushing the intestines and kidneys with Lock's physiological salt solution, and saline catharsis. Bacteriæmia is too rapidly fatal for any benefit to be derived from antibacterial vaccination. The only hope, a very small one, is in removal of the local focus of infection.

The indication for section of the drum membrane is the presence of pus. The indications for mastoid operation in acute and subacute otitis media purulenta are extratympanic extensions, persisting a time after tympanic drainage has been established. The indications for operation in otitis media purulenta chronica are extratympanic extensions of inflammation or other complications. In all complicated cases operative treatment gives quicker and better results than the expectant treatment.

Treatment for improvement of the defects remaining after tympanic suppuration has ceased is important enough to receive special mention. Cosmetic effect sometimes requires the closure of a postaural fistula. Perforation of the drum membrane needs reparative help as previously mentioned. Loss of parts of the sound conducting

mechanism needs mechanical substitutes. Most important is the post convalescent care of suppurative ears. If the drum membrane is closed there is little to do. If a small perforation persists, an occasional inspection is needed to see that the drum cavity remains clear and clean. If there is a large perforation, the patient must be kept under observation at increasing intervals until the lining of the tympanum is white, glistening, and free from the suspicion of crust formations or epithelial accumulations. Otherwise a recurrence of suppuration may be looked for at any time. If there is a tendency for cholesteatomatous formations, the patient must be kept under observation until this tendency has been successfully overcome.

If the case is treated from the start, the prognosis is very favorable for middle ear suppuration and its complications. If the infection is allowed to spread, the prognosis becomes worse with the extension and vital importance of the structures involved, with the virulence of the infection, and with

the inefficiency of the opsonic resistance.

The distinctive blood count is of no practical value, since the general and local clinical findings give much more definite and accurate data on the cause of the case, determine the prognosis, and

furnish the indications for operation.

The bacterial findings are of some use, because the course of the infection is slightly different with the various organisms; for instance, with streptococcus encapsulatus infection the course is apt to be a rapid extension-of the bone involvement with very slight general symptoms. It is noteworthy that with this infection the patient is usually unaccountably free from pain and tenderness.

ILLUSTRATIVE CASES.1

Case I.—A woman, thirty-two years old. Double acute middle ear inflammation of three days' standing, following a cold of two weeks' duration. Mouth temperature, 100° F. Both mastoid tips and antra tender. Double extensive myringotomy, seropurulent discharge. Boric acid solution douching. Intranasal astringents, aromatics, adrenalin. In five days the discharge had ceased in both ears. Perforations closed in fifteen days, and all was healed. Hearing, twenty-five inches for the watch in both ears. Hearing is now normal.

Case II.—A man, aged twenty-seven years. Otorrhœa, five weeks; perforation of posterior, inferior quadrant of the tympanic membrane. Tenderness on pressure over mastoid antrum. Heard watch at thirteen inches. After three days of cleansing treatment, the perforation in the membrane closed. Four months later the watch was heard

at a distance of fifteen feet.

Case III.—A woman, aged fifty-one years. Feetid otor-rhea, fifty years' standing. Had received much treatment at the hands of various specialists. The incus, drum mem-brane, and most of the malleus had sloughed away. Cleansing treatment was used and in two days the ear was healed and has remained so; hearing much improved.

Case IV.—A man, thirty-two years old. Middle ear suppuration for five years; perforation of Shrapnell's membrane filled with granulations; caries of neck of the malleus. After two months of cleansing treatment, suppuration ceased and the middle ear was completely healed. Hearing for Politzer's acoumeter had increased from five feet to thirty-five feet. The ear has remained healed.

Case V.—A man, seventy-seven years old. Otorrhoea of

short duration, mastoiditis, extensive osteomyelitis. Practically no hearing in the ear. Extensive complete mastoid operation. The knee of the sinus and the dura mater of the middle fossa were uncovered. On the fourth day of convalescence the mastoid wound was closed by first intention. Complete tympanic and mastoid healing without suppuration in thirty-nine days. On the fifty-first day watch operated on. Postaural scar scarcely perceptible.

operated on. Postaural scar scarcety perceptions.

Case VI.—A youth, seventeen years old. Chronic middle ear suppuration of several years' duration. An acute ostitis present. Hearing almost nil. Mastoidotympanotomy, on my modified radical mastoid operation, was performed. The ear and posterior wound were wholly healed by the seventh day and hearing became normal. The postaural scar was scarcely discernible on the eighteenth day. There

has been no recurrence.

CASE VII.—A girl, sixteen years old. Chronic purulent otorrhea for three years. Pain in ear, two weeks, headache and dizziness. Schwartze-Stacke radical mastoid operation performed. Mastoid wound healed by first intention. The

performed. Massioid wound neated by first intention. The enlarged middle ear and meatus were solidly healed and completely epidermatized on the twenty-first day. Postaural scar scarcely perceptible and surface smooth. Case VIII.—A girl, sixteen years old. Acuté purulent otitis media for several weeks; hearing very poor. Persistent massioid tenderness. Operation: Very extensive osteomyelitis and large epidural and perisinuous abscess. Dura mater uncovered over a large area in both fosse. Dhra mater introvered see a large area in tour to the middle and the first intention on the fifth day, and the middle ear dry. On the thirty-first day, the watch was heard at five feet. Scarcely perceptible linear,

postaural scar, and smooth surface.

Case IX.—A girl, five years old. Chronic middle ear suppuration, acute mastoiditis, osteomyelitis, epidural abscess, sinus and jugular thrombosis, gangrene of adjacent meninges, cerebral and cerebellar abscess and encephalitis. As much of the diseased tissue was removed as the pre-As much of the diseased tissue was removed as the pre-carious condition of the patient would allow. Jugular vein was full of pus and was excised. Neck and postaural wound completely healed and epidermatized on the fifty-second day. Tympanum healed on the one hundred and forty-sixth day, but the tympanic membrane did not grow again. Watch heard at four inches. Scars scarcely perceptible.

CASE X .- A girl, thirteen years old. Chronic middle ear catarrh with intercurrent acute middle ear suppuration and mastoiditis. Complete mastoid operation. Before the acute attack the watch was heard at twenty-five inches; during the suppuration the hearing was almost nil; after convalescence from the mastoid operation the hearing was twelve feet for the watch, much better than before the operation. Linear postaural scar barely perceptible.

Summary.-With early treatment, prognosis indicates arrest of suppuration, restoration of hearing, and preservation of life. A cessation of the suppuration, and an improvement in hearing is assured, except in the rare, fulminating cases where a fatal issue may be expected. By treatment commenced before the loss of important structures, the hearing may be restored to normal. Fatal results are avoided by early treatment.

THE AUTHOR'S BIBLIOGRAPHY ON THIS SUBJECT.

NEUROMUSCULAR COORDINATIONS HAVING EDUCATIONAL VALUE.

By LUTHER H. GULICK, M. D., New York,

Director of Physical Training, New York Public Schools

This paper does not treat of the entire subject of muscular exercise. It aims only at one of the specific objects of exercise. In order to define the subject it may be well to state the four headings under which we are accustomed to classify the major objects for which muscular exercise is taken,

(1) Medical education. Under this heading come orthopædic exercises, exercises to develop cardiac power, the reeducation and development of a paralyzed member or of a tabetic, etc.

(2) Organic or hygienic education, the general purpose being to increase the general functions of the body, such as circulation, respiration, digestion. This is ordinarily spoken of as "general exercise."

(3) General neuromuscular education. This consists of the bringing to complete function those general neuromuscular coordinations that are desirable for the individual to possess.

(4) Special neuromuscular education, which may be needed for some specific activity or occupation, such as playing the piano, typewriting, playing bil-

liards, handwriting.

This classification does not include those forms of exercise that are taken incidentally in the earning of one's daily bread or in the pursuit of happiness.

This paper relates, then, exclusively to the third heading, namely, general neuromuscular education. It aims specifically to answer the following question: Are there any neuromuscular coordinations which exceed in value from the pedagogical standpoint any other coordinations? Or, to state the question in a different way, have neuromuscular coordinations an equal value from the educational standpoint? If they have not equal value, which coordinations are the most important, and what are the criteria by which we can select the coordinations that are the most important?

I am not referring to that training by which the individual is equipped for specific acts that may be necessary during later life, such as playing the violin, writing, using tools, or any specific acts whatever. I am referring to a general basis of educa-

It is only in recent years that students have given us the neurological data which support the findings of experience in our answer to this question. One of the best studies is the brilliant one of Hughlings Jackson, with his three level theory of epilepsy in its relation to cord and brain. Frederick Burke, in his notable study entitled From Fundamental to Accessory in the Development of the Nervous System and of Movements, formulated and defended with brilliancy one of the essential theses, namely, that in the development of the human being the different parts of the nervous system come to function in a more or less definite sequence, those of a more fundamental character antedating those of a more accessory character. We must not forget the

brilliant work of Clouston on the Neuroses of

Before attempting to answer the question it may be advantageous to illustrate in a concrete way the

nature of the problems involved.

It is conceivable that an individual might be trained to operate the muscles which control the eyes independently. Would such specialized discipline be of advantage or disadvantage to the individual? It is possible, by some means of suitably prepared gymnastic exercises, to train the individual so that he can coordinate movements which to the untrained are entirely impossible, for example, to move the arms in opposite circles. I may move my right arm at the shoulder joint, involving, of course, scapula movements through various right angled positions. It is an exceedingly simple matter to have the left arm do these movements at the same time and in the same way as they are done by the right arm. It is possible to train the individual so that the identical movements shall be involved, but one arm with a movement behind the other, the completed series being finished by the leading arm one count or one movement ahead. The children's trick of patting the abdomen and rubbing the top of the head, and then attempting to change the movements of each hand suddenly, so that the hand that was patting commences to rub and the hand that was rubbing begins to pat, illustrates another exceedingly simple coordination which it is difficult for the person who has not learned it to do.

Some years ago a large volume was written, describing a new system of gymnastics by De Laspe, the fundamental assumption of which was that it was simpler to move one joint than to move two. Therefore, every child should be trained to use each joint of the body in all ways possible. He should then begin to use each joint of the body in all possible combinations with every other single joint of the body. After these two joint coordinations in all possible relations had been accomplished, he should then proceed to train his neuromuscular apparatus so that three joints might be used at once in all possible relations to each other. This process was to be kept up until the individual could do anything with his body of which it was capable. A few illustrations are given at the back part of the large work, showing the kind of movement that would be involved by the pure chance combinations or permutations of movements involved in seventeen joints at once. They remind one slightly of an individual during an epileptic seizure, that is, the movements were absolutely unrelated to each other.

In the light of this book, I would restate the question as follows: Are there any neuromuscular coordinations which tend more strongly than do any other neuromuscular coordinations toward a wholesome development not only of body control, but of the central organ of body control—the nervous system? Are there movements that serve better than others to bring about that growth of tangential fibres which Flechsig has shown to be related to intelligence, and to that relation of dendrite to axon and synapses that promote or afford the basis for wholesome living?

An analysis of the muscular movements made by

a child immediately after birth indicates definite and useful coordinations already functioning with a considerable degree of perfection. Breathing is suddenly established. This in itself is an exceedingly complex act, involving constant readjustment with the different positions of the body, the relations of the spine to the ribs, and the ribs to the abdominal wall, which vary with the changes in abdominal pressure which are due to gravity. Breathing in the horizontal, prone position is not an identical act with breathing in the vertical position. In any position it is a most highly complex series of acts. We find this neuromuscular mechanism ready to use upon the birth of the child.

The hand, actuated as it is by forty muscles, moving twenty-seven joints, functions vigorously as a whole; and since Robinson called our attention to the fact, I presume that all of us have demonstrated for ourselves the high degree of grasping ability that is present in the hand of the newborn child. Sucking and swallowing are acts involving coordinations of muscular groups that are not closely re-

lated anatomically.

The child lies on his back and kicks, breathes, and cries. All of this means that there are thousands of neuromuscular coordinations all ready to use. The coordinations involving the use of the eyes are not perfect at birth, but it takes a relatively small degree of practice—I do not, of course, refer to conscious practice—to develop that control which results in the coordinated action of the eyes. Eye movements as related to neck movements are quickly acquired. The muscles controlling individual vertebrae are never isolated so as to be actuated by the individual, but they can be used serially, as shown by many individuals who have acquired the power to bend in any part of the spine without bending any other part, or to bend with a wavelike motion, the centre of motion extending from one end of the spine to the other.

Standing erect involves most delicate and constant adjustment of nearly all the muscles of the legs, trunk, and neck. While in this position, the movement of one arm forward makes it necessary for the individual to readjust his balance, thereby compelling readjustment of tension from all the groups of muscles involved. In running, jumping, throwing, striking, and in all of the large body activities, practically all the muscles function. They function rather automatically, not as automatically as does the heart nor as automatically as the process of breathing, but they function automatically in the sense that the individual does not think of the muscle, of the part to be used, but thinks of the object to be accomplished. It is a physiological unit which is working.

An examination of the great variety of neuromuscular coordinations that children learn in their ordinary, unguided daily play indicates that the fundamental fact with reference to the progressive coordination of these successive sets of movements is physiological and not anatomical. The body is serving its function with reference to accomplishing given results. This is done by throwing into action successively coordinations which are more or less automatic. Those acts which are "ready to use" that are done at birth are performed without anything more than the preliminary movements made by the child during gestation. They require, some of them, no practice; others, very little. The older the child becomes, the more complete the repertoire of coordinations becomes, the less are the coordinations ready to use, and hence the more is practice necessary. If we view the body as a functional unit it simplifies the case.

That study of anatomy which consists of merely a knowledge of the different systems is superficial and unreal as compared with that knowledge of anatomy which sees muscles, ligaments, and bones as having been developed by having to do specific acts. The act is the fundamental thing which determines the structure rather than the reverse. It is because the hand had to bring the object to the mouth of the individual, for example, that we may account for the insertion of the biceps on the radius rather than on the ulna. Insertion on the ulna would have given the biceps a far greater power as a flexor of the forearm, but one of the particular acts for which the biceps is adapted and which, perhaps, we may assume was one of the acts which helped to produce it, was that act by which the individual reached for an object with the hand prone and grasped it, then bringing it to the mouth, supinated the hand, in order that the palm might bring its contents to the mouth. So the biceps was attached in such a way as to flex the forearm upon the upper arm, at the same time that it was acting as a supinator.

This very clumsy illustration of the priority of use is one that I should carry over into the neurological field, did the space limits of a paper permit.

Let us turn now from muscular acts for physical ends to those muscular coordinations which are done for psychic purposes—the expression of anger, fear, hope, and so on. These demand complexity of coordination following and flowing into each other, never being twice exactly alike, for the conditions which arouse the emotions vary, and the expressive acts of the emotion itself vary correspondingly. A set of such incomprehensibly complex series of coordinations as is involved in the muscles of the face, those of the throat, of the hands, of the back, demands the genius of art to portray-coordinations involving not merely the neuromuscular, but the neuroglandular, involving the intestinal tract, as Mosso has shown, the bladder, and probably all the organs of the body. The whole body expresses the emetion. It is a unitary physiological act, rather than one which is built up by the laborious construction of adding one joint movement to another.

Most of the activities of modern life are built up of those neuromuscular coordinations which have in former times been useful to the race, that is, by great biological units. Even in such technical accomplishments as playing the piano or the violin, using the typewriter, riding a bicycle, and using the scalpel, we are using racially old movements almost entirely. That which is purely new constitutes but an incidental part, although, of course, a necessary part of the total act. Even here the combination is one of physiological units or wholes, rather than of

that are done at birth are performed without anything more than the preliminary movements made by the child during gestation. They require, some individual muscles or individual joints; that is, it is a physiological association as contrasted with an anatomical association of muscular activities.

Turning now to the functioning of the body with reference to psychic states, the feelings which actuate us to-day differ in their objects to some extent from those which actuated us during the prehistoric days of man's life; but we cannot conceive of the fundamental psychic or emotional states as having changed. The study of the stock market is a new thing to think about or to feel about, but it is with the same old emotions of love, hate, fear, ambition, desire, in wonderfully complex ways, that we get the modern phenomenon; that is, here again we are using certain fundamental, unitary acts as contrasted with incidental or isolated mental faculties. The emotions themselves are fundamentally old, even though their application be to new things.

The way in which these emotions take their form in the body is also unchanged, and is the same among all the peoples of all the earth. We speak of thinking and willing, old complex acts—remaining essentially the same, even though we apply them to new things. Thinking in so far as it is motor is associated with the rehearsal of those muscular acts thought of. These are at bottom racially old neuromuscular coordinations. For example, even in such a complex matter as viewing a landscape we form our judgment of distance by eye movements.

I might go on and show how the reconstruction of our conception of the education of the body from one of associating anatomical groups to viewing it as a physiological whole is at present reconstructing psychology. It is but recently that we have ceased to hear of a faculty of attention, a faculty of memory, of will, and the like; whereas we now know that there are as many different kinds of attention as there are different kinds of things to give attention to, and that there are as many different kinds of memory as there are different kinds of things to remember. With this crumbling of the faculty psychology there has fallen that theory of education which has aimed to train each faculty by itself and then adjust it to the other faculties. This is precisely the fate of that conception of physical education which aimed to train each muscle or joint and then coordinate it with the others.

Thus we find a violent contrast between that which is logical and that which is pedagogical. It is logical to build up muscular movements, but we find it to be against the whole tendency of children. We find that normal children learn the successive acts involved in plays and games with ease, that feeble minded children may be measured in their feeble mindedness pretty accurately by the extent to which they have learned those neuromuscular coordinations that have been common to our kind. We cannot think of man becoming fundamentally different with reference to the relation of structure and function than he is now. He will continue to live a life of love, of hope, of fear, of desire, as he is living now; and he will express these old emotions in ways which are intelligible now. Therefore, for the child to learn his plays and games, his running, jumping, striking-all that play which involves skill of hand, coordination of eve and hand-

is fundamental with reference to his psychic activity, for he functions as a whole. It may be true that the time will come when man may no longer need to run or even to walk, but we cannot conceive of a time coming when the adult man will not need to have learned to walk when he was at the proper age, because of the bearings of this upon his neuromuscular system. His failing to learn to walk might be to his nervous development somewhat as the cutting off of a tadpole's tail is to its subsequent development, or better, the omission of the gillslits in the human embryo. Adult man has no use for gillslits, but if the gillslits were lacking in the embryo, the blood circulation in man could not have developed in its present form.

Thus we see that not merely general neuromuscular coordinations should be taught to children, but specific ones, highly complex ones, racially old ones. To do the opposite tends towards the breaking down of the structure that has been built up through all the ages. To train the eyes to move independently would be to move away from sanity and wholesomeness. It would tend to break up that coordination of impressions and the unity of that

act which we regard as visual thinking.

These coordinations are historically old. They are the kind of movements that have meant success. They are the kind of movements because of which our forefathers survived. The man who could run and jump and throw was better fitted to survive than the man who could not do these things with an equal degree of skill. Upon this basis the whole emotional and intellectual life is built. This accounts to some extent for the fact that the kinds of coordinations of which I have spoken-athletic sports, plays, and games-are interesting to children as formal gymnastics are not interesting.

Thus, true physical education is not to be accomplished by the teaching of segregated muscular movements, but by the orderly development of increasingly complex movements which are racially old, which involve good posture of the body, which train the individual to express predominantly emo-tions consistent with modern life. These movements are to be expressed in terms of physiological acts to be accomplished, certain wholes, rather than

as anatomical parts to be moved.

I have tried to show:

I, The unitary character of our neuromuscular as well as other acts:

2, that they exist in racially old combinations: 3, that we inherit these coordinations, or at least

a strong tendency toward them;

4, that mental, moral, ethical, social life is built on these

We should therefore in our physical instruction educate:

I, In physiological units;

2. Toward racially old and inherited tendencies. This paper is already so long that I can but suggest what should be discussed under the general

heading of the nature of the curriculum through which the child should be led.

This consists first of the unguided plays of babyhood. During this period no instruction is necessary. Opportunity for free activity, rolling, kicking, and the like, is enough. The impulse within the child will lead him to perfect such mechanisms as are then developing. Following these come the games and sports of childhood. Here the child needs help. In old communities, suitable games are passed on from generation to generation of child life without adult aid; but in a country like ours, particularly in our great cities, made up largely of peoples from different countries, different villages, these play traditions are lost. They need to be restored to children by skilful teaching; not by formal instruction, but by that informal leadership which the well equipped adult can give.

The old rhythmical movements which have been found among all the primitive peoples and in all civilizations have crystallized in the dance. These folk dances express in extraordinarily complete form man's history-the sowing of grain in the spring, the reaping in the fall, the chase. In fact, all of man's life has been portrayed and crystallized in these art forms, which we in America have allowed to die. They must be resurrected and given again to the children as part of their birthright, as a fundamental. part of their education—not merely muscular education, but emotional education, for in these great plays and games of the world it is the whole individual that is called into activity. In this fact lies their extraordinary interest and value.

It is true that because of the school desk with its deforming tendencies we need to have special exercises that shall tend to overcome these deforming effects; but aside from this, the general curriculum of neuromuscular activities involved in physical education should be that based upon the physiological unit type found in the plays, dances, and games referred to.

500 PARK AVENUE.

ARTIFICIAL HYPER. EMIA AND ITS THERAPEU-TIC APPLICATION (AFTER BIER).

By Algernon Brashear Jackson, M. D., Philadelphia.

Surgeon to Mercy Hospital; Surgical Assistant, Polyclinic Hospital.

Although more than fifteen years have elapsed since Professor August Bier began to treat tuberculous lesions by artificial hyperæmia, it has been but recently that the procedure has been generally accepted as a rational method of treatment by the physicians of this country. Now that this form of treatment has proved so successful in the hands of judicious operators, the wonder is, that in view of our comprehensive knowledge of physiology, the method has remained so long unrecognized and un-

Long has it been known and observed that all organs of the body functionate only in the presence of hyperæmia. Further, it has been noted that the invasion of any foreign substance or body is attended by an increased hyperæmia to the part affected. To Bier this process of Nature was a lesson, and he has simply aided natural forces to

hasten the curative effect already begun.

To be an intelligent adjuvant to Nature in the therapeutic application of hyperæmia, one must recognize the physical and chemical differences between the rapidly flowing arterial blood and the sluggish venous stream. As yet our knowledge of the subject is limited. A failure to recognize the sort of hyperæmia at which Nature is striving may produce more harm than good, in the employment of artificial hyperæmia. But since a knowledge of the component parts of the blood and their action is always hanging on the ragged edge of doubt, Bier prefers to apply hyperæmic treatment as hyperæmia per se.

Hyperæmia has been divided into active and passive, which may be interpreted to mean arterial and venous. Active or arterial hyperæmia is that form in which there is an increased flow of arterial blood to the part while more blood flows in. Passive or venous hyperæmia is that form in which more blood is held within the part by a diminished outflow of venous blood, which is also referred to as stasis hyperæmia. However, this classification but aims at the truth, for many times it is difficult to say whether the hyperæmia is active passive, or mixed.

It shall be the aim of this article to briefly discuss the methods of producing artificial hyperæmia, its effect upon the parts treated, and more particularly to deal with the therapeutic application of the same by citation to cases treated by the author both in private practice and hospitals.

Production of Artificial Hyperæmia.

Certainly the oldest and best known method of producing local active hyperamia is by the application of heat. For thousands of years physicians have treated localized inflammation after this manner without knowing that the good effects derived were brought about by the production of a localized active hyperamia; the accelerated blood stream to the part acting as a cooling agent upon the inflammation. This heat is applied in various ways, such as hot water bags, hot compresses, hot mud, sand, poultices, and hot air. The last named agent is much employed because of the vast amount of heat that can be borne when administered in this form.

The form of hyperæmia that has most interested me for some time past is the passive variety produced by the stasis bandage. "Bier's stasis" is a familiar term employed by surgeons in referring to hyperæmic treatment for ununited fractures. But Professor Bier declines the honor of originating this method, and makes the following very interesting statement which I take the liberty to quote. "It seems that the first to have hit upon the idea to make use of artificial stasis hyperæmia in insufficient callous formation was Ambroise Paré. In the thirtieth chapter of the thirteenth book of his works he at first recites the remedies for the reduction of callus when too large. These consist in diminishing, dividing, and astringent substances, and he thus continues. 'If however, the callus is too small and undeveloped in consequence of the bandage being too tight, or because the limb has been too long at rest without exercise, or the nutrition of the patient was insufficient, the bandage has to be taken off and entirely removed from the fracture. Instead a different kind of bandage should be applied beginning at the root of the vessels, if on the leg close to the inguinal region, if on the arm near the shoulder, and reaching nearly to the seat of the For by this remedy the blood is squeezed and and compelled to those to the injured place."

The above quotation is made merely to show how long ago this useful method of treatment was employed, then forgotten, and now revived and placed upon a logical and scientific basis.

In the production of passive hyperæmia by the stasis bandage there must be an understanding in the mind of the operator as to the result desired, and how it may be obtained. The rubber bandage is applied above the part to be treated by making several circular turns so as to compress the walls of the veins but not those of the arteries. I always make it a practice to find a pulse below the bandage and am never satisfied until I do. The changes noted (upon the arm and hand, let us say) when the bandage is lightly applied are at first a swelling of the veins, a bluish discoloration of the arm, palm of the hand bright red, in which can be observed minute white spots. These changes are noted during the first hour. After the third or fourth hour the hyperæmia becomes more marked, and a mild cedema presents itself, which can be proved by strong pressure of the finger upon the part. The longer the bandage is applied, the more marked becomes the cedema. The mild application of the stasis bandage with the results outlined above may remain from ten to twenty hours without producing any inconvenience to the patient.

A vigorous hyperæmia may be produced in a very short time by a firm application of the bandage, but this is dangerous because it leads to cold stasis, and, I believe, should never be employed. For the production of stasis hyperæmia a broad rubber bandage should be used, and not small rubber tubes that cut into the skin and are always applied with a degree of uncertainty as to the amount of pressure produced. When I wish to congest a finger I always apply the bandage above the wrist, thereby congesting the entire hand, because a small cutting rubber tube about the finger or toe misses the mark ninety-nine times out of a hundred. If continuous daily application of the bandage is desired it is advisable to change its location from time to time in order not to injure the tissues by compression.

Another method of producing hyperæmia is by suction apparatus. As early as 1834, Junod described such an apparatus known as "Junod's boot." A short description of the same may be interesting. Imagine four glass or copper cylinders, so shaped as to fit the four extremities, to which are attached at each end a broad rubber ring, which is bound tightly about the limb, so as to make the receptacle airtight. An exhaust pump is attached to the cylinder, and by this means the air upon the inside is thinned. Enough of this. One has but to observe the various forms of suction apparatus at the instrument stores to see how Bier has taken this idea as a guide for the modern application of the same treatment. It is difficult to say which sort of hyperæmia is produced by suction, but most all who have given the matter study agree that both active and passive are brought into play.

Hyperæmia produced by "derivantia" and "revulsivia" are among the oldest relics of medicine. I simply mention these methods in passing. I hope it may stimulate study, for back of the production of hyperæmia there is always a principle which must be considered if a favorable result is to be had

The Effects of Hyperamia.

It would seem useless in an article such as this to enter into a full and complete discussion of the effects of hyperæmia. The therapeutic value of this method of treatment, with an incidental discussion as to the effects produced in cases cited, will, I believe, serve a better purpose. However the temptation is great and in a measure I must yield to it.

The most immediate effect of hyperæmia is the reduction of pain. This statement in itself seems a contradiction to the older teaching, that blood stasis always produced pain. True, pain is always present where blood stasis is the result of foreign insult, not however because of the blood stasis per se, but on account of injury to neighboring cells and nerve endings. Rather does blood stasis in the part aim to bring relief to the injury. The analgesic effect of hyperæmia is a prominent factor in the treatment of acute and chronic rheumatism, with its painful stiff joints, gonorrhoeal arthritis, and arthritis deformans. I say it is an important factor in their treatment, first because it relieves pain, and secondly by so doing restores mobility to the stiffened joints. In these cases, however, the hyperæmia must be prolonged and continuous. The pain caused by traumatism, fractures, leg ulcers, frost bite, acute or chronic infection, and such pathological conditions is relieved by hyperæmia. I have not yet met with a case in which stasis hyperæmia was indicated and properly applied, that has not been relieved of pain by its application. The application of a stasis bandage should never increase pain. If it does increase pain it is the result of faulty technique on the part of the operator.

When one observes how successfully acute infectious diseases are treated by stasis hyperæmia, the question naturally arises as to the cause of the good results obtained. There must certainly be some force or forces brought about by hyperæmia which act directly or indirectly antagonizing bacterial invasion. Several theories have been advanced, but as yet they are all uncertain. Experiments have shown that pyogenic bacteria are rendered less active and in some instances practically inert by prolonged hyperæmia. Investigators differ as to the cause. Some cling to the theory of phagocytosis brought about by an increased number of leucocytes to the infected part. Others assert that the carbonic acid gas which is held by the venous blood is the bactericidal agent. Certainly it is passive rather than active hyperæmia that shows the most pronounced effect upon invading organisms.

In view of the fact of the various theories I have seen propounded, I have often wondered why the theory of the opsonins has found no place in this discussion; however I may have overlooked such literature. In passive hyperæmia the venous blood is confined to the area of infection by the stasis bandage, and more blood laden with leucocytes is flowing to the part, hence there is an increased localized phagocytic action due to artificial stasis. If according to Wright's theory that this power of leucocytes to incorporate and destroy bacteria depends upon elements in the blood known as opsonins, then it seems reasonable to say that the more leucocytes present the greater the opsonic power. This power is necessarily increased when the leuco-

cytes are held at the seat of infection, while at the same time more are flowing to the infected area. Therefore to me it seems probable that there is a localized increase of the "opsonic index" brought about by physical means (the stasis bandage) which confines the leucocytes and renders their phagocytic action more pronounced because their quantity is increased. As yet, however, the bactericidal effect of hyperæmia is in a great measure theoretical, but the results are positive in the treatment of acute infectious diseases.

Both active and passive hyperæmia act as solvents, while active hyperæmia acts as an absorbent. The nutritive value of tissues is increased by active arterial hyperæmia. The author will endeavor to show these various effects by cases which have come under his care.

Therapeutics of Hyperæmia.

My first experience in the employment of hypermia was in the treatment of localized infections by the stasis bandage. The first results were discouraging, and I was about to regard the method as a fad, and not of real therapeutic importance, when suddenly I awoke to the fact that the fault lay within myself and not the method. In some instances I increased pain, and in others I created pain where there was little or none before. The cause of this was a too tight application of the stasis bandage. It requires experience to regulate the pressure in such cases, and after deftness is acquired, the pain is always lessened and the results are more encouraging.

I shall cite one case which serves as a type of my first errors in technique:

Case I.—A young lady came into my office with an infection of the middle finger, around the nail, which was slightly painful. A rubber tube was tied rather tightly above the area of infection. The pain began to increase in a few minutes. I bade her to be quiet for a while and the pain would soon disappear. Instead it grew worse. For an hour she waited in my office and the pain became intolerable. The finger was blue and cold, so I removed the tube, applied a wet dressing, and referred the patient to next day for treatment. Upon the second visit the condition was worse; tube was applied again, but not so tightly as the day before, however, with the same painful results. At that time an incision was made, blood flowed, but no pus; wet dressing was again applied, and tube abandoned. Next dressing showed the presence of pus, which was treated by irrigation, drainage, and wet dressing with good results.

Several, in fact many, such discouraging results made me have little respect for the value of artificial hyperæmia.

I will next cite a case to show how well hyperæmia acts when proper technique is employed.

Case II.—A young man with infected thumb came to the surgical clinic at the Polyclinic Hospital. I applied lightly a stasis bandage above the wrist, and the pain was relieved almost at once. Three hours afterward I saw him at my office. The entire hand was slightly hyperemic, but still free from pain. The bandage was removed for about one half hour; pain began in fifteen minutes. The bandage was again applied and twelve hours later I saw the patient with no pain and a marked hyperemia of the hand. For three days the infection was treated by ten hour stasis and two hours rest for two periods of the day, and at the end of that time there was no pain or swelling; still neither had incision been made nor wet dressing applied.

The purpose in referring to these two cases is at once apparent. In the first case my technique was

wrong, and in the second it was evidently correct. It took a number of unsatisfactory results to put me upon the right trail. The three most important lessons to me are: (1) Do not apply bandage too tightly. (2) Use a broad rubber bandage and not a small cutting tube. (3) Apply bandage high above the seat of infection, thereby congesting a greater area than that invaded by the disease. I have treated many such infections in this way, and ofttimes have found it necessary to make incision to evacuate the pus, and have applied wet bichloride dressing, but so quickly has the condition cleared up, that I am convinced that the passive hyperæmia did a great good.

At Mercy Hospital I treated a case of tuberculous cervical adentits by suction alone. The application was daily for four weeks, but the result was positive and I have not heard of any recurrence. Another such case was admitted to the wards of Mercy Hospital, which had been incised elsewhere. The wound was left open, suction was applied daily which drew from the wound quantities of blood, pus and broken down gland tissue. In three days the swelling began to disappear. In two weeks the wound had healed with slight scar and no evidence of tumefaction which so frequently accompanies such conditions when treated by other means.

Many cases of acute and chronic arthritis I have treated with the stasis bandage with good results. At first the pain is relieved and motion restored by the solvent effect of the hyperæmia. I have had no experience with hot air apparatus, because in neither hospital nor private practice have I the facilities for applying this method for the production of active hyperæmia. Certainly in cases of acute or chronic arthritis, active hyperæmia should be employed for its absorbitive effect for short periods, after a prolonged application of passive hyperæmia by the stasis bandage. In arthritis I have been accustomed to apply stasis bandage for twelve to eighteen hours daily with an intervening period of rest. The bandage is always applied so lightly as to give no inconvenience. In several instances, after the patient is up and moving about, I have shown him how to apply the bandage, and in most cases he has been greatly benefited by my instruc-

I might continue to cite case after case with varying results, but such would be useless. My purpose is to contribute my mite to this method of treatment. Even in the last few months, since I feel that I have learned my technique well I have met failures in some cases. Such must come to everyone. No therapeutic measure is absolutely infallible, and such must not be expected of hyperæmia. I believe the method worth more than a mere trial. It is worth a continuous effort on the part of every practitioner, and will soon be adopted universally wherever intelligent medicine and surgery are practised. What has been my success can be another's, if he will give the whole matter careful attention. Up to this time I have treated more than two hundred cases by hyperæmic methods, and am becoming firmer in my conviction each day that it is one of the most conservative methods yet to be introduced into surgery. Careful application of hyperæmia will make unnecessary many mutilating surgical operations with their consequent pain and scars. There are many cases to which hyperæmia cannot be applied because of location, but I believe constant study of this method will bring about increased facilities and devices.

All life is hyperæmia, hence hyperæmia is as old as life. The application of this functionating principle to therapeutics is but another example of man's ingenuity which harnesses the forces of Nature and makes them do his gentle bidding.

770 SOUTH EIGHTIFNIH STREFT.

THE STOMACH AND INTESTINAL GASES.

With a Description of an Apparatus for their Collection and Analysis.*

By Seymour Basch, M. D., New York,

Attending Physician to the German Polikhnik, Department of Diseases of the Stomach.

(Concluded from page 689.)

THE APPARATUS.

The apparatus with which all these analyses were made was devised by Professor N. Zuntz, of Berlin, and myself. After a demonstration before the Berlin Physiological Society, Professor Zuntz (25) published a detailed description of the apparatus, together with an explanation of its working principles and a record of the various tests made to verify its accuracy. In view of this, I shall limit the present discussion to such technical details as are essential to a proper understanding.

At the outset, it must be understood that the apparatus was devised and is intended only for the analysis of such gases as are of common occurrence in the alimentary canal, viz., carbon dioxide, oxygen, nitrogen, hydrogen, marsh gas, and allied hydrocarbons.

The carbon dioxide and oxygen are determined directly through absorption by certain chemical solutions. In each case, the amount of contraction of the gas mixture equals the volume of the oxygen or carbon dioxide that was present.

Inflammable gases must first be burnt in an excess of oxygen or of a gas mixture, such as atmospheric air, that contains a known amount of oxygen. The percentage of hydrogen and of marsh gas, etc., is determined from the amount of the ensuing contraction and the carbon dioxide formed.

The apparatus, therefore, consists essentially of two parts, the one, a (see Fig. 1), being for the measuring of the gas mixture and the absorption of carbon dioxide and oxygen, and the other, b, for the combustion of the inflammable gases, hydrogen and the marsh gas series. The two parts are closely connected by short, thick walled rubber tubing of small calibre; thus leakage or the accumulation of gas between the parts is prevented.

gas between the parts is prevented.

The parellelopiped shaped glass box seen in Fig. 1 is 40 cm. high, and rests upon a four legged metal stand. It is filled with water in order to maintain a uniform temperature in the gas mixture while in the burette tubes a and b. At its upper end the glass box is fitted with a light, metal collar, to which

Read in part with a demonstration of the apparatus used at the annual session of the American Gastroenterological Association, Atlantic City, June 3, 1907.

are attached the absorption pipettes d and e. One of these, d, is for carbon dioxide. It is filled with a strong caustic potash solution, in which are many pieces of narrow glass tubing. The pipette e is for oxygen, and contains a number of small pieces of

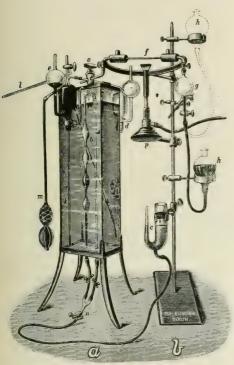

Fig. 1.-Apparatus for gas analysis.

copper gauze tightly rolled into cylindrical shapes. These are placed in a mixture of four volumes of concentrated ammonium carbonate solution with one volume of caustic ammonia solution of specific gravity 0.91. The lower, free openings of the pipettes are securely closed by rubber stoppers.

The gas burette consists of the tubes a and b placed vertically in the centre of the glass box, and passing out below through two round holes in the bottom of the same. A rubber tubing slipped over each lower burette end prevents the escape of any water, and serves also to connect the burette with the Y shaped glass tube n. Each of these rubber tubes is furnished with a pinchcock. Above, the burette tubes a and b are united by a short, curved glass tube, 4 mm. in diameter. Upon the upper surface of the latter is a short, straight, vertically placed glass tube whose interior is continuous with that of the curved connection tube, and whose upper end widens out to receive a tightly fitting glass stopper o. The burette tube a has four elliptically shaped enlargements, above and below each one of which there is a horizontal circular marking. The space

between every two markings holds 10 c.c. of gas. The tube b is of uniform calibre throughout, and has 12 c.c. of its interior space marked off in subdivisions of 0.05 c.c.. The zero point is at the uppermost horizontal marking of the tube a, and the rest of the markings continue down the tube b. The entire measuring space therefore equals 52 c.c. As in all glass burettes, the accuracy of each measurement must be verified by careful testing, and a record of any errors preserved.

Four short, thick walled horizontal capillary tubes pass off at right angles to each other from the glass stopper receptacle of the burette; their lumina communicate with that of the burette. Three of these tubes are straight, and their outer ends communicate respectively with the external air and the absorption pipettes d and e; the fourth tube has its outer end curving upwards at nearly a right angle and is connected with the combustion apparatus B. All of these connections are made by means of thick walled capillary rubber tubing fastened by fine copper wire to the glass and metal tubes.

The glass stopper o is supplied with an interior boring which curves upward from the centre of its lower surface to the middle of one side. The latter opening is at the level of, and communicates with, the inner opening of each of the four horizontal glass capillary tubes. Thus, by successive turns of the stopper o through 360° , the burette space may, at will, be completely closed off, or else brought into communication with the outer air, the absorption pipettes, or the combustion apparatus.

The long arm of the Y shaped tube n is connected by a long rubber tube with the levelling glass c, the peculiar shape of which is seen from the cut. This tube is furnished with a screw pinchcock. The levelling glass and the rubber tube may be filled with mercury, but it is better to use a lighter fluid that absorbs little or no gas. We always employed a saturated sodium chloride solution, faintly acidulated with hydrochloric acid, and colored yellow with rosolic acid. By the proper turning of the

Fig. 2 .- Apparatus for the collection and termentation of gases.

stopper o, and the raising or lowering of the levelling glass c, the salt solution is made to rise or fall, and air or gases can, at will, be drawn into or forced out of the burette and the absorption pipettes.

The double balloon bulb seen in the cut is attached to a long glass tube, whose end, guarded by a piece of rubber tubing, dips down to the bottom of the water. A uniform temperature of the water is obtained by blowing air from time to time through the water. The vertical glass tube k, standing in the water, is weighted down with metallic mercury. Its lumen measures 50 c.c. and communicates with that of the graduated tube l, from which it may, however, be closed off by a stopcock. The two tubes constitute a thermobarometer. A drop of petroleum is placed in the lumen of l, and any variations in the temperature and atmospheric pressure in tube k result in a corresponding change in position of the petroleum drop. The area of k being known, the effect of any alterations in atmospheric and temperature pressure upon the volume of gas under analysis can be readily figured out.

That part of the apparatus used for the combustion experiments is an adaptation of Drehschmidt's (26) modification of Orsat's original device for burning gases within a platinum capillary tube. Prior to this, the method employed for determining inflammable gases was that through their explosion in the presence of an excess of oxygen and an indefinite amount of oxyhydrogen gas. This was both tedious and cumbersome. The essential part of the combustion apparatus under discussion is the narrow platinum tube f. Within its lumen is a fine platinum wire. The ends of the tube pass into two hollow copper jacket boxes and are there soldered to two small brass tubes. The latter emerge, one from each of the copper boxes, and curving downwards pass through and slightly beyond the rounded ends of a flat, brass, arcshaped band, fastened to the burette stand. Binding screws secure the brass tubes to the brass band. The copper boxes contain water for cooling the heated tubes. The free end of the one brass tube is connected with the absorption apparatus as already explained; that of the other is connected by thick walled capillary rubber tubing with the glass bulb g, whose lower end tapers into a glass capillary tube fitted with a stopcock. This capillary tube is connected by a reavy rubber tube with a second glass bulb k. The latter contains sufficient metallic mercury to more than completely fill the bulb g. This is accomplished by opening the stopper in g, and raising the bulb h to the necessary height, as indicated by the dotted figure.

If the stopper o be turned towards the combustion apparatus, and the stopcock in g be opened, the gas mixture may be drawn from the burette through the platinum tube into bulb g, or driven in the opposite direction by merely lowering or raising the

mercury bulb h.

Whenever a stomach or intestinal gas mixture is to be analyzed, the copper jackets must first be filled with cold water, and the stopper a brought into communication with the exterior air. Stopcock g is then exceed, and the mercury driven from bulb h to g. The interior of the burette is next washed several times with the rosolic acid salt solution by raising and lowering the levelling glass c. The burette and the horizental air communicating glass capillary are left full of the solution, while the pinch-

cock n is tightly screwed down. The gas mixture container is now connected with the burette; the capillary rubber connecting tube, if desired, may be temporarily fastened by copper wire. If the volume of gas to be analyzed is 12 c.c. or less, tube b only is filled; if more than 12 c.c., tube a is first filled. Care must be taken to adjust the lower level of the gases to one of the horizontal markings on the tube filled. Whichever tube is being filled, the corresponding pinchcock below that tube is opened, while that of the other tube is left closed. By carefully opening the screw n and fastening glass c, as shown in the illustration, below the level of the burette, the salt solution will slowly flow out of the burette and the gas mixture be drawn in. When the burette is filled, stopper o is turned off again, screw n tightened, and air is blown through the water jacket. The gases are given a short time for adjustment. Their volume and the standing of the thermobarometer are then noted, whereupon the analysis proper may begin.

Stopper o is turned toward pipette d (for carbon dioxide absorption), the levelling glass c is talen in hand, the both pinchcocks below the burette, as well as the screwcock n, are opened, and the glass c raised until the gases are driven into pipette d. They remain there but a few seconds, when, by lowering the levelling glass and manipulating the screw and pinchcocks as before, they are again drawn back into the burette. Uniform temperature of the water being secured, the gases are given a few seconds for adjustment, and their volume and the standing of the thermobarometer again noted. The stopper o is then turned towards pipette e for oxygen absorption. The same procedure is gone through as with pipette d, excepting that the gases are permitted to remain about three minutes in e, on account of the slower absorption of oxygen,

The gas mixture is now ready for combustion. is first driven into pipette d, and left there while the stopper is turned and an amount of pure oxygen or of atmospheric air, more than sufficient for complete combustion, is drawn into the burette. This amount is measured off and noted. It is then mixed with the gases in pipette d, and the whole drawn back into the burette. The Bunsen burner p is now lighted, care being taken not to heat the platinum tube beyond a bright red. Stopper o is next turned toward the combustion apparatus, the bulb h taken in hand and carefully lowered so as to insure a slow flowing of the mercury out of bulb g. This action also draws the gas mixture slowly out of the burette, through the heated platinum tube, and into bulb g. As soon as the salt solution reaches the curved end of the glass capillary connected with b, bulb h is slowly raised and the gases driven back into the burette, thus undergoing a second combustion while passing through tube f. When bulb g has become completely full, its stopcock is turned off and the Bunsen burner removed. The gas cools off very soon in the burette; a reading is taken in the usual way, and the thermobarometer's registration is also noted. Finally, the gas mixture is driven into the pipette d and the amount of carbon dioxide that was formed, determined.

This really completes the analysis. If desired

the correctness of the analysis, as determined from the amount of contraction and the volume of carbon dioxide formed, may be verified by measuring the residual oxygen. From this, the volume of oxygen burnt may be learned, and the hydrogen and marsh gas estimated.

After completion of the analysis, the combustion portion as well as the absorption pipette d should be "washed" with nitrogen so as to be ready for the next analysis. For this purpose the residual nitrogen may be used, or atmospheric air drawn into the burette and freed, by absorption, from its oxy-

gen and carbon dioxide.

The collection and fermentation apparatus was secured through a modification of a device employed by Zuntz and Loewy in some blood investigations. It is simple in construction, easy of manipulation, and cleanly in handling. It can be used not only to obtain stomach contents and intestinal gases, and to hold them indefinitely without leakage, but also for the artificial thermostatic development of gases

from stomach contents and fæces.

As shown in Fig. 2, it consists of a pear shaped glass vessel of about 300 c.c. capacity, into which is fitted a large solid rubber stopper. Two thick walled capillary glass tubes each about 7 inches long, pass vertically through the stopper and end, the one (a) flush with its inner surface, and the other (b) 5 mm. beyond the same. To this protruding end there is fastened by fine wire, a thin rubber bag of such size that, when distended, it completely fills the interior of the glass vessel. Exteriorly, each tube is bent in its middle to an angle of about 110°, and on its free end has a short piece of thick walled rubber tubing fastened by copper wire. Each rubber tubing is supplied with a screw pinchcock.

When using the apparatus for collecting stomach contents or intestinal gases, a little water is placed into the pearshaped glass vessel and the rubber stopper with the rubber bag inserted. The stomach or rectal tube is next attached to the rubber tubing on a through a short glass connection piece, and water squirted from a syringe into the thin rubber bag until the latter completely fills the interior of the glass vessel. This forces the water and air from the pearshaped vessel out through the stomach or rectal tube. The latter is then introduced into the stomach or rectum, and by suction, the water is drawn from the rubber bag back into the syringe. A negative pressure is thus created in the glass vessel, and the stomach contents or rectal gases, as the case may be, are thus drawn into it by aspiration. When a sufficient amount has been collected, the pinchcock on a is screwed down and the apparatus detached from the tube.

In the case of the direct fermentation of fæces or of stomach contents, these, if not already of fluid consistency, are made so through the addition of water. They are placed within the pearshaped glass vessel, and the bag and stopper inserted. All the air and a little of the fæcal or gastric mixture are then driven out of tube a by squirting sufficient water into the bag. The pinchcock on a is then screwed down very tightly, and the entire apparatus placed in a thermostat until sufficient gases for analysis have developed. As these collect, a corresponding amount of water is forced out of the rubber bag through tube b.

Whenever an analysis of the gases is to be made, the rubber tubing a is attached to the analytical apparatus, as already described, and a little extra water is squirted into the thin rubber bag. The pinchcock on a is then screwed slightly open, and the gas mixture drawn in as already explained. The analysis being started, the collection apparatus is detached, and, if desired, may be allowed to ferment further after more water has been forced into the rubber bag and the screw on tube a tightened. no more gas is required, the rubber stopper and bag are taken out and the entire apparatus washed.

¹⁴ EAST SIXTIFTH STREET.

CASE OF LEPRA TUBEROSA. By JEROME KINGSBURY, M. D., New York.

This case was presented by the writer at the March meeting of the Society of Dermatology and Genitourinary Surgery, and since then at several other clinical societies. The patient attended the evening clinic at the Skin and Cancer Hospital for over two months, but is now an inmate of the City Hospital on Blackwell's Island.

History. Ernst G., twenty-six years of age, born in Courland, Russia. When a boy he worked with his father who was a fisherman, but for the past ten years has been who was a insterman, but for the past tell years has been a sailor. He had made a number of deep sea voyages, but never visited any ports in the tropics, being generally employed on American coasters. Leprosy is endemic in Courland, but according to the patient's own statements he never knew or heard of anyone in his native place who had the disease. Family and early personal history was negative. Six years ago he suffered from an attack of pleurisy with effusion, but otherwise his general health had always been good. No history or evidence of syphilis As far as could be ascertained there did not

seem to have been any change in his sexual

functions.

About two and a half years ago the man noticed that at night his legs would often be swollen. There was no pain, but he had occasional chills. The swelling of the legs increased and persisted for nearly three months. About this time lumps began to appear over the shins. At first they were small and few in number, not more than half a dozen. These gradually increased in size, however, and soon new ones appeared to the best of the state of the size of the state of the size. on the calf and thighs. Later the arms and forearms became affected, and about nine monts ago a single nodule appeared on the forehead. There had been diminished sensation in the arms and legs for nearly one year. About four months ago the man had what was undoubtedly an acute leprous exacerbation. There was moderate fever, the lymphatic glands became enlarged, and the left leg was red and swollen. He was admitted to Bellevue Hospital and remained in the erysipelas pavilion for over two months. He first came under my observa-

tion at the Skin and Cancer Hospital shortly after his discharge from Bellevue. Examination. The patient weighed one hundred and twenty-five pounds, and was about five feet seven inches in height. He had light hair and the skin on unexposed and unaffected parts was very fair. He was not very well developed although wiry and fairly strong. There was general though

moderate adenopathy.

Physical examination showed the heart and lungs to be in normal condition, and no enlargement of the spleen was made out. No reaction obtained from the conjunctival tuberculin test. This was employed merely as a matter of interest because marked reactions have been frequently reported as occurring in nontuberculous lepers after the injection of tuberculin. Urine and nasal se-cretions were examined for lepra bacilli with negative results.

The cutaneous lesions varied in size, from papules the size of a pin head to flattened tumors three quarters of an inch in diameter. There were not more than five, however, of this latter size. These were soft and reddish brown in color. There were nearly forty nodules that were about the size of a split pea on each of the upper extremities. The larger number of these lesions were found on the extensor sur

There were about sixty similar nodules on saces. There were about sixty similar nodules on each thigh and probably half of this number on each leg. Several papules on the soles resembled those seen in syphilis. There was a tubercle on the forehead about three eighths of an inch in diameter. It was soft and velvety, but showed slight telangiectasia on the surface. This was the only lesion on the face. On the arms and thighs were numerous minute yellow papules. These for the most part were closely aggregated and many had coalesced. Quite a number of these papules had invaded an old vaccination cicatrix on the left arm. The trunk was free of lesions. There were superficial scars on the right elbow and left thigh, the result of recent trauma. On the legs there were numerous dark pigmented areas that showed the site of previous nodules. Right leg showed slight swelling, and the skin was shiny and blueish red in color. The left leg is now apparently of

The ulnar nerves were but slightly thickened and there was no contracture of any of the fingers. Peroneal nerves were a little enlarged, but the great auriculars seemed normal. There were but few areas of complete anæsthesia, although sensation was diminished in the forearms and legs. Several areas on the back showed hyperæsthesia.

There was no seborrhœa of the scalp, but the hair was

Leprosy simulating sarcomatosis.

dry and thin. Probably half of it had been lost. The beard was scanty and the eyebrows, particularly at the outer third, were exceedingly thin. There was hardly any suggestion, however, of the characteristic facies of the

A nodule excised from the forearm was sent to the Presbyterian Hospital Laboratory for microscopical examination, and I am indebted to Dr. Meakins, the resident

pathologist, for the following report:
Microsections show large masses of lymphoid and epithclioid cells with many large giant cells. With staining for bacteria the giant cells and many epithelioid cells are shown to be crowded with lepra bacilli-

39 WEST THIRTY-NINTH STREET.

FOREIGN BODIES IN TRACHEA AND STOMACH

By WALTER LATHROP, M. D., Hazleton, Pa.,

Surgeon in Chief, State Hospital.

CASE I.—A. G., age eighteen, was brought to the hospital at 7,30 p. m., in the evening of July 6, 1908, with a history of swallowing a dime, some four hours earlier; and since then had been unable to speak above a whisper, had great distress in region of throat, some coughing, and dyspnæa

A physician who was called early advised her removal to a hospital; the x ray was used and the coin was plainly

Table knife, nine and three quarter inches long, removed from stomach and esophagus

seen rising and falling with each movement of the trachea. She was told the danger of leaving it alone, also the danger of opening the trachea. She decided to risk the operation, and was speedily prepared, and chloroform administered; a free incision was made, not rapidly, but with care; all bleeding checked, the trachea was opened low down, and the incision extended to the thyreoid cartilage. The coin lay at one side, was grasped by a small forceps, and removed. The wound in the trachea was closed by catgut stutures, as were the other structures. The operation was completed in eight minutes. The patient reacted

tion was completed in eight minutes. The patient reacted well; the wound healed primarily, and she was discharged in a week with her voice restored.

Case II.—C. H., age twenty-six, German; came to the hospital on the evening of July II, 1908, and gave history of having swallowed a table knife, at 3 p. m., that day. He stated he had no pain, but was worried about it; the man was somewhat under influence of alcohol, and his story was doubted by all who heard the table. The x ran did not was doubted by all who heard the tale. The x ray did not show anything, owing to the shadow of the vertebral column. He was advised then to have an exploratory operation performed, but declined emphatically, and left the institution. Twenty-four hours later he again appeared, and said he would remain and have the operation, as he had

pain in the epigastrium.

He was prepared carefully for operation, and the next morning a laparotomy was performed; the stomach drawn up, and a hard object felt. On incising the stomach, I re-moved, much to my astonishment (as well as all who were present), a long, black handled table knife, which had extended up into his oesophagus, and rested by the handle on the anterior wall of stomach. The incision was carefully closed by double row of continuous sutures, with Pagen-stecher thread. The incision into the abdomen was closed throughout, and the patient put to bed. He reacted well, and was in the best possible condition for twenty-four hours, when his pulse shot up to 140, and in a few hours he was dead, with symptoms of gastric dilatation, and suffocation. Before his death he told us that the evening he first came, he took emetics and tried to disjodge the knife. after which he became worse, and was glad to have the

An autopsy was performed, which revealed several severe lacerations in the œsophagus and cardiac end of the stomach, showing the effect of his emetics. Had he submitted to operation when he first came, I believe he would have recovered. The wound in the stomach was entirely closed

and in fine condition. His heart was very much dilated. The knife was nine and three quarters inches long; the blade was one inch wide. The case is reported as one of unusual interest, in the line of foreign bodies in the

TRAUMATIC INSANITY. By J. W. HARTIGAN, M. D., Morgantown, Va.,

Fermerly Professor t Anatomy in the West Virginia State University.

The patient was a male, forty-two years of age, a German by birth, by occupation a mechanic. Family history without fault. This man had been occupied at public works in this community for years. He had always borne an enviable reputation, industrious good natured, liked by all who knew him. He was a member of a local German club, where he was a universal favorite. Roomed and boarded in a house with a young man from his own country, of whom he was extremely fond, acting as a father to him, lending him money and paying his board when out of employment

On April 6th, without provocation and without motive, this patient, arriving at his boarding house at 10 p. m., entered his friend's room and shot him to death, also shooting

tered his friend's room and shot him to death, also shooting at another roomer occupying the same room with his friend. Twenty minutes after the murder the murderer was found asleep in his own room, which adjoined that of his murdered friend. He was arrested and placed in jail.

I examined him during his incarceration in the the jail with three other physicians, and found the following conditions: Right pupil dilated under all conditions, left pupil normal. Delayed intellection. Apparent progressive paralysis of right forearm and hand group. Inability to shake hands with his right hand. Pain in head all the time, would stift for hours quietly with his head buried in his hands. Insit for hours quietly with his head buried in his hands. Inability to remember the movements necessary to make the

letters of the alphabet or to write from mental initiative or from dictation, though he could recognize the letters when asked what they were. No recollection of his crime, stoutly denying it, and declaring that the murdered man was his best friend.

His case came on to trial for murder, for which he was acquitted on the ground that he was of unsound mind at

the time of the commission of the crime and now. The evidence before the jury brought out the fact that he acted in a queer manner for some months before the murder. One instance was cited that he had blown the whistle repeatedly at the works where he was employed at any hour, irrespective of quitting time, and that he had some years before sustained an injury to the head by being struck with a chisel with such force as to knock him down and to render him unconscious, and from the effects of which he had been in bed with an attack of brain fever for six weeks. Before the court to answer hypothetical questions, I

Before the court to answer hypothetical questions, I stated that his old injury might have left him with some pressure effects which might account for his present mental condition. After much questioning by the presiding judge and such suggestions as I could offer, the court turned him over to me for treatment and operation if I saw fit to operate. He would have been sent to the asylum had he not presented some points of hope after the operation. He was removed from the jäll under competent guard, and after studying him for some time, on June 10, 1908, I op-

erated upon him.

I expected to find a depression or a thickened meningeal area. The initial opening was small, with no membrane at all under the opening; instead a vacant space. I enlarged the opening sufficient to admit a finger, and at the bottom of the depression I could plainly feel the brain pulsate. On withdrawing my finger material of the consistence of thin tar adhered to it. After working some of this loose the brain promptly rose up and filled the cavity-the size, I should say, of an English walnut. Some of the brain substance came away with the gauze used in sponging. Suddenly the hæmorrhage became so furious that I was sure I had opened the longitudinal sinus. I tried repeatedly to check the hæmorrhage with gauze, but was unsuccessful. I finally packed enough to control the bleeding, and closing the wound got the patient off of the table as soon as possible. I allowed the pack to remain forty-eight hours, removing it without trouble and without the slightest hæmorrhage. The wound healed without further dressing, and after the first seventy-two hours, during which time I kept the patient under the influence of sedatives, he appeared to regain all his lost functions.

He has now been at his work for over four weeks, fully restored in every particular. He has been discharged by the court as cured. The accompanying photograph will show better than I can explain the localization area.

This patient gave a history of having had loss of use of right foot, right leg, right shoulder, though when I saw him only the muscles named above were at fault. Unfortunately no ophthalmoscopic examination was made in this case.

THE CURE OF INGUINAL HERNIA UNDER LOCAL ANÆSTHESIA.*

By Albert S. Morrow, A. B., M. D., New York,

Adjunct Profes or of Surgery in the New York Polychine; Attending Surgeon to the Workhouse and New York City Home for the Aged and Infirm.

According to Berger's statistics, the proportion of those suffering from hernia is forty-four in one thousand. It has been stated that there is a loss in the earning capacity of those so afflicted amounting to from fifteen to fifty per cent. (1). Aside from this economic standpoint, however, and what is vastly more important, is the fact that an individual with a rupture always has a possible source of death from strangulation. Two alternatives are offered to these patients: (1) Radical cure by operation; and (2) wearing a truss.

The radical operation, on account of the reasonable certainty of cure and the comparatively short detention from business, is one of the most successful of surgical procedures, yet it is safe to say that but a small proportion of those afflicted with a hernia choose this means of relief. This is too well

opening the second of the first the second of the second o

attested by the large number of trusses yearly manufactured and sold to the public to require further comment. The reason for this can be found in the words of Da Costa, that "the radical operation is almost without danger in properly selected cases. General anæsthesia must be held responsible for this qualified statement. While I am willing to admit that the number of deaths from general anæsthesia may be small, still this danger strongly appeals to the patient. This apprehension, coupled with the unpleasant after effects of general narcosis, deters many from accepting a means of cure that we can be reasonably sure will be permanent. Improvement in the anæsthesia alone is necessary to popularize what is already from the surgeon's standpoint a most satisfactory operation. To-day we do not hesitate to open an abscess, amputate fingers, remove ingrowing toenails and external hæmorrhoids under local anæsthesia, but with a hernia—simply because it is classed as a major operation—general narcosis is considered to be essential. Yet the operation for inguinal hernia, on account of the superficial position of the structures, the limited area involved, and the ease with which the sensory nerves supplying the region of operation can be identified and cocainized, is one that above all others is adapted to local anæsthesia.

This paper is based upon a study of twenty consecutive cases in which the radical operation was personally performed under local anæsthesia. These were not selected cases, and so can be considered

fairly representative.

Anatomy.—To secure success, an accurate knowledge of the situation and course of the nerves supplying the field of operation is essential. These nerves are but three in number, namely, the hypogastric branch of the iliohypogastric, the ilioinguinal, and

the genital branch of the genitocrural.

The iliohypogastric nerve, derived from the first lumbar and at times from the eleventh and twelfth thoracic in addition, divides into an iliac and a hypogastric branch after piercing the transversalis muscle near the middle of the crest of the ilium. hypogastric branch continues in a direction downward and inward toward the linea alva, lying between the internal oblique and transversalis muscles, to both of which it supplies twigs and inosculates with the ilioinguinal. Near the internal abdominal ring it gradually passes through the internal oblique muscle, and, gaining the space between the internal and external oblique, runs downward and forward. Becoming superficial by piercing the aponeurosis of the external oblique a little above the external ring, it terminates by supplying the skin of the suprapubic region. It will be found in the upper angle of the hernial incision after reflecting the aponeurosis of the external oblique, usually running downward and inward on a line drawn from near the anterior superior spine of the ilium to a point about an inch above the external ring.

The ilioinguinal, also derived from the first lumbar, and at times additionally from the twelfth thoracic, accompanies the hypogastric nerve between the internal oblique and transversalis muscles as far as the iliac spine, lying, however, on a somewhat lower level. It supplies twigs to both of these muscles, and then, piercing the internal oblique about half an inch internal to the iliac spine, passes down

in the inguinal canal. Emerging at the external ring to the outer side of the cord, it distributes branches to the skin of the upper inner side of the thigh, the pubic region, penis and scrotum, and labia in the female. The ilioinguinal nerve is smaller than the hypogastric and in some cases it may be absent, in which event its place is taken by the genitocrural. Usually it will be found in the line of incision, just beneath the aponeurosis of the external oblique and on a lower level than the iliohypogastric, running downward in the long axis of the hernia. It may even lie as far outward as Poupart's ligament.

The genitocrural nerve, derived from the branches of the first and second lumbar, divides high up into a crural and a genital branch. The genital branch enters the external abdominal ring and traverses the inguinal canal, lying internal to and below the spermatic cord. It supplies the cremaster muscle, and may also send twigs to the internal oblique and transversalis muscles, and terminates by supplying the skin of the scrotum and adjoining portion of the thigh. It will be found, after reflecting the aponeurosis of the external oblique, lying among the structures of the cord; frequently it lies

behind the cord.

From this brief description it will be seen that sensation in the inguinal region is presided over by three fairly large nerve trunks, which have a certain definite position and are so situated that cocainization is performed with ease and certainty; and that, furthermore, if all three nerves are found and cocainized, pain sensation in the entire field of opera-tion will be abolished. Practically, however, it is not absolutely necessary to cocainize all three nerves, for if either the iliohypogastric or the ilioinguinal is cocainized the operation can be performed quite as painlessly by simply infiltrating in sensitive regions supplied by the uncocainized nerves. In all of my cases was I able to find at least one of the nerves. In nineteen of the iliohypogastric and ilioinguinal were both found; in that one case the ilioinguinal was missing. In six cases was the genitocrural found. Thus in less than one third of the cases were all three nerves found, yet the operation was performed in a satisfactory manner.

Solution Employed for Anasthesia.- In all cases cocaine has been employed, using a freshly prepared 0.2 per cent. in hot normal salt solution for the skin anæsthesia, and o.1 per cent. solution for deeper infiltration. The solution must be freshly prepared, for, as is well known, cocaine solution quickly develops a fungus and in a short time may produce suppuration. It is used warm, at the body temperature, to increase the effectiveness of the anæsthesia. Normal salt solution is employed instead of water, because, as pointed out by Matas (2), it is isotonic with the blood serum. Such a solution, producing neither swelling nor shrinkage of the cells, does not cause pain and has no injurious effects upon the tis-Other local anæsthetics have not been tried, for it has been found that cocaine answers all purposes, producing certain and complete anæsthesia without injury to the tissues, and in the strength mentioned is safe and nontoxic. Less than one grain of cocaine, and often less than half a grain, will suffice for the entire operation. This amount injected intermittently for an hour or more is abso

lutely safe. Bodine reports over 400 hernias done under local anæsthesia without a single case of cocaine poisoning (3). In 7,000 cases of cocaine anaesthesia Reclus has not had a death that could be

attributed to the cocaine (4).

Technique.—The technique employed is the same as described by Bodine in 1903 (5). About half an hour before the operation 1/4 grain of morphine is given hypodermatically. This serves a three fold purpose; it allays any nervousness the patient may have, it deadens sensibility somewhat, and, lastly, it is the physiological antidote for cocaine. The table on which the patient lies should be made as comfortable as possible by covering it with several folded blankets or an air cushion. The patient should be told to assume as comfortable a position as he can, with the arms folded over the chest or under his head, but entirely free. If so inclined he may read, smoke, sip a cup of tea, or occupy himself in any way that will distract his attention from the operation. The field of operation must be very gently and carefully washed. The nurse doing this must be instructed to confine her attention to the region of operation and not pour quart after quart of solution over the entire abdomen, as is so often done, and then leave the patient saturated in a pool of chilly water. Observance of these small details gains the patient's confidence, and prevents restlessness, complaints of cramps, and backache before the operation is half completed. The line of incision is cocainized with a 0.2 per cent. solution of cocaine. The needle should be held at an angle of 45°, and is pushed into the malpighian layer of the skin. If it is inserted properly its point will be visible just below the skin surface. A few drops of cocaine will produce a weal the size of a ten cent piece. The needle is reinserted into the edge of this weal and more solution injected until the entire line of incision is one long weal. In this way the first prick only of the needle is felt by the patient. Then with a 0.1 per cent, solution the subcutaneous tissues are thoroughly infiltrated, especially in the neighborhood of the external ring. After the incision is made through the skin and subcutaneous tissue, any dissection about the external ring should be postponed until the nerve trunks are cocainized, as their terminal branches supply this region. It is better to go right down to the aponeurosis of the external oblique, incise this structure, which can be done painlessly without additional cocaine, and cocainize the nerves. One or both the iliohypogastric and ilioinguinal will be seen lying upon the internal oblique muscle as white cords when the aponeurosis is reflected. One or two drops of a 0.2 per cent. solution of cocaine are now injected into and around each nerve, after which the dissection about the external and internal rings may be completed. The cord is dissected from the sac, care being taken not to touch or pinch the vas, as such a procedure causes the patient most excruciating pain, similar to that produced when the testicle is pinched. The opening of the sac may be painful in some cases; this seems to be especially so in hernias of short duration. In such cases the sac has been found to be very much more sensitive than is the thick sac in a hernia of long standing. Infiltration into the sac along the proposed line of incision will obviate complaints in these cases. The interior of the sac is then inspected and the contents are dealt with as may be deemed necessary. Trendelenburging the patient will cause nonadherent contents to return to the abdomen without the necessity of any handling. To avoid pain in ligating the sac it is well to twist it into a cord and infiltrate about the neck at the point where the ligature is to be applied. The sac can then be transfixed, ligated, and amputated painlessly. The operation is completed as in an ordinary case, using any of the methods for repair of the canal that the operator may desire.

Pain.—The patient's version as to the painfulness of the operation will vary according to the individual. What one might regard as pain will pass unnoticed by another. Some have declared the entire operation to be less disagreeable than the shaving and preparation before it. Others have said that it was no worse than having a tooth filled. In no case has a patient done more than give facial or verbal expression of the pain. The pain has never been severe enough to make them squirm or jump, nor has it as yet been necessory to complete the operation under a general anæsthetic. The amount of pain inflicted can be regulated to a great extent by the operator. Rough handling and pulling on tissues must be avoided. Clear cut dissection only is allowable, for it must be remembered that cocaine only deadens pain sensibility, it does not abolish the perception of touch. A fidgety, nervous operator will of necessity inflict more pain than one who makes every move and each cut count for something. There is no doubt that every time a bloodvessel is cut or clamped it gives the patient a twinge of pain. It is a mistake to tell a patient that the operation will be devoid of pain, and the next moment give him a sudden shock by clamping some bleeding vessel and then insist you have not hurt him. This repeated several times causes him to quickly lose confidence in the operator, and he soon becomes nervous, restless, and apprehensive. It is far better to anticipate each little twinge and prepare the patient by telling him what to expect. Failure to observe these little details is responsible for many failures in cocaine work and results in unjust condemnation of the method, though the fault lies with the operator.

Completeness of Operation.—It is contended by the opponents of this method that it is impossible to perform as thorough an operation as with the patient under a general anæsthetic. This is a mistake, for if the cocaine is used properly there need be no curtailment of the operation in any of its steps. Without entering into a discussion as to the merits of individual operations, I will say that I have witnessed or performed a majority of the recognized methods of closing the inguinal canal. A brief sumary of the cases operated upon will furthermore give an idea as to some of the conditions met with.

The hernias varied in size from that of a hen's egg to the size of a child's head. They were of from six weeks to thirty-five years' standing. The youngest patient was sixteen years old, and the oldest sixty-two years. In four cases it was necessary to ligate and amputate omentum, which was done without additional pain. Two of the cases, however, suffered mild shock, lasting several minutes. In three cases it was necessary to separate adherent gut. One case was a traumatic hernia, in which the hernia protruded through the internal oblique in

two places, the nerves being embedded in scar tissue, a condition resembling that found in recurrent Two cases were congenital, requiring the formation of new tunics for the testicles. In half the cases the sac was very adherent to the cord, necessitating careful dissection for the separation of these two structures. In a case of strangulated femoral hernia, not included in the above, 4 inches of gut was resected. Two cases that had been previously operated upon for hernias on the opposite sides under general anæsthesia declared that all the pain they suffered was preferable to the discomfort produced by the general narcosis. In a case of double hernia, the first side was operated upon under local anæsthesia, and, the patient, being given his choice of anæsthesias and for the second side, chose local anæsthesia again. These cases represent fairly well the general run of hernias, and in all of them local anæsthesia was found entirely adequate to deal with the conditions encountered.

Advantages .- I. All danger of death from anæs-

thesia is avoided.

2. The disagreeable after effects of general anæsthesia, such as nausea, vomiting, and backache, are absent; consequently there is no danger of the stitches being separated or torn out from the strain of vomiting. A person need only remain in a ward and compare the convalescence of a hernia immediately after ether and a similar case after the use of local anæsthesia to be convinced of the superiority of the latter; on the one hand we have a patient nauseated, vomiting, and but half conscious, with the prospect of twenty-four to forty-eight hours' fasting added; on the other, a patient in possession of all his faculties, with none of the above unpleasant symptoms, and who an hour or two later will be found eating a light meal with relish.

3. There will be fewer cases of suppuration, because gentle handling of the tissues is imperative; hence there will be but a small amount of trauma

inflicted.

4. Under local anæsthesia the integrity of the nerve supply to the inguinal region is preserved, hence there is less danger of recurrence. Cutting a nerve, as is well known, produces thinning, atrophy, and paralysis in the muscles supplied. On this point Cushing (6) cites the effect of cutting the genitocrural nerve in operations for varicocele, the effect being atrophy of the cremaster and consequent sagging of the scrotum on that side. The necessity of preserving the integrity of the nerves supplying the inguinal region has been very strongly emphasized by Bodine (7), and I agree with him that many of the recurrent hernias (exclusive of those due to infection of the wound) are the result of the destruction at the time of operation of the nerves supplying the lower fibres of the abdominal muscles. This would seem to be borne out by the conditions of the parts in recurrent hernias. Seldom has the line of suture given away; instead there is a thinning of the new formed muscular wall, allowing the hernia to redevelop.

5. For strangulated hernia local anæsthesia is especially adapted; or, in the words of Bodine, "It rises almost to the dignity of an imperative method." These cases are generally already overwhelmed from toxic absorption and in more or less of a precarious condition. The additional strain of a general anæs-

thetic, aside from the danger of the patient drowning in fecal vomit, frequently produces just that much more shock than the patient can stand, and it is the experience of many to have such cases die on the operating table from the anæsthetic. Again, local anæsthesia furnishes abundance of time for the restoration of the circulation in gut of doubtful vitality without adding a particle to the shock or danger for the patient. Hot towels may be applied to the intestine almost indefinitely, if necessary, and the operation then be completed. In the meantime the patient remains as comfortable as he would be if in bed. If the gut is gangrenous, resection may be performed or a temporary fistula may be established without the use of additional cocaine. In this connection I will again cite the case of resection mentioned above as an illustration:

Mrs. B. W., age eighty-seven, was operated upon for a small size strangulated femoral hernia of at least thirty hours' standing. At the time of operation she had a rapid, irregular pulse and fecal vomiting, with all its attendant symptoms. On opening the sac a small knuckle of gut was found to be black, and the application of heat for over half an hour failing to change its appearance, four inches were exsected and an end to end anastomosis was performed. This was done without any complaint on the part of the patient, save when the mesentery was pulled upon. The she complained that "her back felt as if it were breaking. The patient was returned to bed in even better shape than before the operation, but fecal vomiting continued and she died twenty-four hours later. Bodine reports a case of strangulated inguinal hernia in which he resected eleven inches of gut without pain under local anæsthesia (8)

Conclusions.—It is my conclusion, based on experience in these cases, that local anæsthesia is an ideal anæsthetic for inguinal hernia, and that in a large proportion of cases the operation may be performed absolutely without pain, and at most the pain inflicted during the entire operation will be less than that produced in opening an abscess or an infected finger.

Therapentical Aotes.

The Sterilization of Catgut.-Dr. Kusnetski (Roussky Vratch, 1908, No. 18) describes his method of sterilizing catgut. He places the catgut threads for eight days in a one per cent. solution of iodine and potassium iodide and for three hours afterwards in a solution of 21/2 drachms of iodoform in 61/2 ounces of ether, 2 pints of alcohol, and 11/2 ounces of glycerin. The threads are then rolled on a sterilized glass spool and placed in a glass vial which is not sealed hermetically at once, a short interval being allowed in which the catgut may dry out.

Gallstone Colic .- Any stomach or duodenal inflammation in gallstone colic, remarks a writer in the Journal of the American Medical Association, should be relieved by daily saline laxatives, perhaps best the effervescing sodium phosphate, and the administration of bismuth and soda three times a day, one hour before meals:

- breakfast.
 - M. ft. chartulæ 20.

Sig.: A powder three times a day, one hour before meals. The diet for a few days should be similar to that for catarrhal jaundice, viz., free from fat. In other words, milk is not a good diet. A little dry toast, broiled lean meat, as steak and chops, hot tea and poached eggs allow sufficient change of diet for a few days. Cold drinks of any kind should not be taken, but plenty of water should be given daily. If there is constipation there should be a daily laxative, as sodium phosphate, or any other saline. If there is jaundice, daily hot baths are advisable.

If there is believed to be chronic congestion of the bile passages, the drinking of a glass of hot water an hour before meals is beneficial. Also ammonium chloride is indicated in this condition, and this drug is just as valuable in subacute inflammation of the bile passages as it is in the subacute inflammation of the bronchial tubes. It may be administered for this purpose as follows:

Ammonium chloride, M. Sig. A teaspoonful in plenty of water, three times a day, after meals.

If the ammonium chloride is very disagreeable to the patient, it may be administered in simple carbonated water or in vichy.

The repeated administration of so called cholagogues, or drugs that are supposed to increase the flow of bile, is not good treatment. Calomel is a cholagogue only in its ability to cause a complete cleaning out of the upper part of the intestine, and is certainly often indicated, but should not be frequently repeated. Salicylic acid preparations somewhat stimulate the secretory activity of the liver, but it is hardly advisable, in the treatment of the condition under discussion, to give a drug so foreign to the system as is salicylic acid. Of course if there is intestinal fermentation and a salicylate. as salol, is indicated, it should be given. A mineral acid, as dilute hydrochloric, or dilute sulphuric, or dilute nitrohydrochloric acid, seems at times to increase the flow of bile to the duodenum, as the duodenum objects to acid and strives to neutralize rapidly any acid that reaches it. These acids, then, sometimes seem to increase the flow of the bile, but except for a short period could not be of any value in disturbances of the gallbladder.

It may be well to repeat the necessity for daily thorough evacuation of the bowels, and this should be accomplished by a saline, preferably, or by an aloin, rhubarb, or cascara preparation, as seems best

to suit the patient.

NEW YORK, SATURDAY, OCTOBER 17, 1908.

PELLAGRA IN THE UNITED STATES.

We are accustomed to associate pellagra with the peasantry of Italy, who subsist to a very great extent on polenta, which is usually prepared by boiling corn meal, often of poor quality, in salt water. The North American continent, to which maize is indigenous, was long supposed to be exempt from the disease, and as a matter of fact the supposition was probably well founded. The apparent anomaly of the virtual exemption of the home of maize from a disease attributed to eating maize has been explained by the theory that American climatic conditions are better adapted to the production of the cereal than those of most other countries are, and that consequently our maize is free from those deleterious qualities, whatever they may be, that appear to be the cause of pellagra.

But within recent years there has appeared in our southern States a disease which, says Passed Assistant Surgeon C. H. Lavinder, of the Public Health and Marine Hospital Service of the United States, is "possibly true pellagra." The bureau has recently issued a pamphlet, by Dr. Lavinder, which gives a succinct account of our present knowledge of the disease. He remarks that "there is reason for believing that perhaps this disease may be quite prevalent, but unrecognized." "Since it is of a serious nature," he adds, "and epidemic in character, knowledge concerning it is becoming of much importance to the American physician, and more especially to the practitioner in the southern States."

Cases have been reported from Georgia, Alabama, Texas, South Carolina, and North Carolina. Examination of these reports, says Dr. Lavinder, seems to show definitely that probably for several years past there have appeared in the southern United States sporadic cases of an unrecognized nature resembling pellagra, and that within the last year or two the disease has increased rapidly in the number of cases and in the extent of territory involved. Though in some respect the disease seems to differ from the pellagra of the Old World, it bears a close resemblance to it. The cases are mostly acute and the mortality is high.

If, says Dr. Lavinder, the cause of pellagra is accepted as a diet of spoiled maize, the American maize crop must within recent years have undergone a decided change in some respect, "for maize has always been very extensively used as food in the southern United States, and pellagra has not appeared in former years." He properly remarks that this question will call for extensive investigation if the disease should continue to advance. There can be no doubt that such a staple article of food as Indian corn is in this country must not be allowed, even to a limited extent, to degenerate into a source of serious disease. We take it that what ought to be found out first is the nature of the change which may have taken place in the grain, which is generally thought to be effected by some fungus. The Department of Agriculture, which perhaps has already given attention to the matter, may certainly be counted on to conduct whatever investigations may be required.

THE NEW TREATMENT OF TABES DORSALIS.

When Duchenne, in 1858, made the far reaching and definite deduction that this much dreaded affection was conditioned on degeneration of the sensory neurones, which gave rise to a definite tissue alteration in the posterior columns of the spinal cord, neurologists felt that an advance had been made toward a clearer understanding of a process which had before been involved in much mystery. Succeeding generations of trained workers have verified his teaching, and at the present time there is a fairly conclusive body of unassailable facts-anatomical, physiological, and clinical-to substantiate the views held by the profession. The most recent work of Wassermann, Plaut, Levaditi, and others has almost demonstrated beyond a doubt that syphilis is generally the primary cause of the disease.

One would think that such a mass of evidence was not to be lightly disturbed, but all is now changed. A new prophet has declared that erosions of the middle third of the urethra in men, perhaps of the cervix uteri in women—it seems unfortunate that a woman's urethra is so short—are the cause of tabes dorsalis. This thesis, originally promulgated over a year ago and supported by more or less colossal misinformation, was again brought forward by Dr. Le Grand N. Denslow at a recent meeting of the New York Academy of Medicine, and as a consequence it has received a good deal of newspaper notoriety. Yet, strange as it may seem, we should not think it worth while to mention the matter but for the fact that one of the high priests of neurology in New York has seemed to lend the hypothesis his support.

Dr. Denslow's original paper was published in the Medical Record for June 15, 1907. In his last paper, recently read but not yet published, the product of his theorizing has been more positively set forth. In 1907 the cure was probable; in 1908 it seems absolute. All great therapeutic discoveries are simple, after all: so is this one. The erosions must be carefully treated with topical applications, sounds are passed, and minute incisions may be needed; but, mirabile dictu, these measures require such a skilful adaptation of means to ends that ordinary physicians are apt to put the lives of their patients in peril if they attempt to follow the lead of the master-the modern magician's wand, though of steel, can safely be wielded only by the discoverer of its new field of usefulness. To such lengths are we come! And the New York Academy of Medicine has been made use of to promulgate such a doctrine and such procedures! But, the results! The people look for a sign, and Dr. Denslow's patients are improved; at least so declares one whose name is held high in professional esteem!

Where lives the man who has not mitigated some cases of locomotor ataxia? Surely the results now brought forward do not compare with those of Fraenkel, of Bern, but he never alleged a cure. Is it not a commonplace of neurology that remissions are frequent in tabes, just as they are in paresis? What man of ordinary experience has not seen patients improve under appropriate treatment for vesical complications, and what member of the profession has not instilled a hopeful view of life into these patients and produced striking amelioration of certain symptoms in many persons sunk into the slough of despondent fatalism? What more has the new treatment of tabes shown? Nothing.

A committee of the New York Neurological Society appointed to report on the circumstances attending the reading of Dr. Denslow's paper has expressed its findings in words which are recorded in our news columns, in which we would emphasize the following sentence: "Your committee further be-

lieves that before such 'cures' are exploited they should be submitted to the most rigid investigation." This report correctly sets forth the attitude of the scientific mind, which is characterized by being open to conviction, but requiring adequate proof before accepting a startling innovation. The facts set forth in support of the new hypothesis are so far not sufficient to warrant its acceptance and certainly not sufficient to warrant its widespread exploitation in a manner calculated to give false hopes to the public.

RABIES.

Relatively to its extreme rarity, there is probably no other disease which excites so much comment, inspires so much fear, is so costly, or has such extensive influence on state medicine. Rabies, being generally recognized as incurable, could scarcely lead to a malpractice suit; the lack of power to control its cause is such that it would be difficult to show legal responsibility in a damage suit; no engineering problems are connected with it, as in the case of typhoid fever; and it is not of the economic importance to call for such institutions as are beginning to be developed for the treatment of tuberculosis. Yet its ultimate influence on medical jurisprudence is greater than that of almost any other disease. Dog ordinances are founded on the fear of it. Such ordinances constitute a precedent for a very special form of taxation; they confirm an old and generally condemned precedent that those who execute the law should derive no immediate benefit from its enforcement, since the dog tax frequently goes to the police pension fund or some similar fund; they upset a very ancient custom of protecting private property, for it has been held that a dog chained to a tree or doorway, so as to be unable to harm any one but a trespasser or thief, must also be muzzled; the work of dog catchers is harrowing to humane persons and either shocks or brutalizes children: the destruction of small animals tends to encourage official recognition of private societies to prevent cruelty; the payment of traveling expenses and treatment at institutes of a private nature is an extension of the degree of relief afforded to the indigent sick by the local government in the case of sickness and injury in general, and is a precedent for a form of paternalism which is regarded with disfavor by most citizens and political economists.

In spite of this popular feeling, a small but considerable minority contend that there is no such disease, that it is as much a myth as the influence of the "dog days," and their action is not now accepted by any scientific critic, although its popular acceptance is shown in the annual recrudescence of the

enforcement of the "dog laws." Hydrophobia, says this minority, is either hysteria or tetanus or some other form of infection. We can very readily dispose of the question of hysteria. Any disease may be hysterically imitated, and hysterical fear has occasionally produced death. In few other instances is the element of suggestion so active as in the case of dread of hydrophobia. The indefiniteness and length of the period of incubation and the almost complete limitation of symptoms to the neuromuscular apparatus predispose to hysterical mimicry. Therefore we must admit that even a fatal case of "hydrophobia" may be purely hysterical. On the other hand, to assign all reported cases to hysteria would be the height of folly. There can be no question as to the actuality of hydrophobia in the clinical sense; the real issue is as to whether we are dealing with a disease sui generis or one which is merely the manifestation under peculiar circumstances of an infection well recognized in general. While we might assume that the symptomatology of so called hydrophobia might be duplicated by infection with any one of several pyogens, the pneumococcus, Diplococcus intracellularis, etc., the only definitely established infection which could be considered as generally inclusive of the symptomatic type of hydrophobia is tetanus.

The late Dr. D. Hayes Agnew used to say that no one who had seen both tetanus and hydrophobia could confound them. Still, with all respect to this eminent authority, it must be borne in mind that even tetanus is a fairly rare disease. Very few men see more than single cases in a lifetime, and hardly ever any large series at once. Most physicians never see hydrophobia. The great majority of reported cases are unique experiences for the reporters, and only by great sacrifice of time and money could any one man acquire anything like the experience which the routine practitioner may have in most diseases. We think it must be admitted that, from the purely clinical standpoint, there is no greater difference between tetanus and hydrophobia than exists between different forms of tuberculosis, cerebrospinal meningitis due to any one bacterium, mild and "black" measles, etc. This is especially true when we consider that the very symptom which has given rise to the popular name of the disease and imitations of the barking and writhing of a mad dog are now generally regarded as hysterical obsessions, even if the attack itself is genuinely infectious.

From the pathological standpoint, the extreme rarity of an infection is an argument against its specificity, unless this rarity is explicable by artificial control, as in the case of smallpox, or by other factors, such as the relative degree of segregation of the originators and the limitations of exposure

of human beings, as in the case of equinia, anthrax, etc. The comparative rarity of tetanus has been regarded as well explained by the necessity of an hermetically sealed wound to insure anaerobic conditions, and it is altogether probable that, whether hydrophobia is tetanus or a distinct infection, the same requisite must be fulfilled. Still, hydrophobia is rare even as compared with tetanus. The latter, indeed, occurs rather frequently as a stable epizootic of a mild type. Hydrophobia, if it exists at all, is capable of infecting nearly every warm blooded animal, being by no means confined to the dog, and, in particular, it involves various wild types of canine animals which are decidedly gregarious. Indeed, the domestic dog is much more gregarious, or at least much more free to come in contact with other animals of its own species, than the horse and other domestic animals. Thus, if hydrophobia were a distinct disease and not an exaggerated type of tetanus or other infection, we should expect epizootics on a considerable scale, both in a state of nature and in that of domestication.

THE INTERNATIONAL TUBERCULOSIS EXHIBIT.

The size and generally meritorious character of the exhibit made in Washington in connection with the recent International Congress on Tuberculosis made it highly desirable that the exhibit should be brought to New York, for here it will probably be visited by many more persons even than were embraced in the throngs that viewed it in Washington during the three weeks that it was on view. There seems to have been no trouble about getting the consent of the exhibitors, foreign as well as American, but the raising of a certain sum of money for the purpose was found necessary. The amount was not large, and as we go to press we learn that it has been obtained, the city having made a generous appropriation toward it. We understand that an unexpended balance of several thousand dollars was left over from the Congressional appropriation for the expenses of the congress, and it would have been perfectly proper, we think, to apply that residue to aid in defraying the cost of the undertaking.

AGAIN THE DOCTOR IN GENERAL LITERATURE.

It is not for the first time that we now record our satisfaction at the incursion of Dr. Carl Beck, of New York, into the domain of general literature. He has recently produced a charming little book'

Sonnenblicke com laternischen Amerika, etc. Berlin. Leonhard

of travel in the West Indies and Central America. Dr. Beck's journey took him to Jamaica, Colombia, Panama, and Costa Rica, lands with which the people of the United States ought to be better acquainted. His narrative is illustrated with half tone reproductions of interesting photographs, and the text itself is very readable. The proofreading has not been all that might be desired, otherwise we should not find German custom carried to the extent of inserting a comma after the word voi in the hackneyed quotation Lasciate ogni speranza, voi The legend under a cut on the same ch'entrate. page (page 106) contains the expression "Santa Domingo," and so does the one under another cut on the opposite page.

Rews Atems.

Changes of Address.—Dr. D. S. D. Jessup, to 542
West One Hundred and Twelfth Street, New York; Dr. Charles H. Jaeger, to 471 Park Avenue, New York; Dr. G. H. Clapp, to 3808 Spruce Street, Philadelphia; Dr. William J. Dugan, to Suite 305 Flanders Building, Philadelphia; Dr. O. Kiliani, to 50 West Seventy-seventh Street, Manhattan Square Hotel, New York.

Medical Greek.—It is announced that a Greek translation is being prepared of Dr. Achilles Rose's book entitled Medical Greek.

Medical Greek

Personal.-Dr. John F. Erdmann has been appointed professor of surgery in the New York Postgraduate Medical School and Hospital, and has resigned his clinical pro-

The Health of Dr. William T. Bull.—As we go to press we regret to learn that the illness of this eminent New York users. Bull is not yet an old man, however, and it is to be hoped good ground for expecting his recover

Medical Society of the County of Richmond, N. Y .-The regular meeting of this society was held at the Staten Island Academy on Wednesday evening, October 14th. Dr.

Island Academy on Wednesday evening, October 14th. Dr. Anthony Bassler, of New York, read a paper entitled Early Diagnosis of Gastric Carcinoma, which was discussed by Dr. Patterson and Dr. Baldwin.

The Medical Society of the County of Ulster, N. Y., will meet in the City Hall, Kingston, on Tuesday, October 20th, at 2 p. m. Dr. Mark O'Meara will read a paper on The Present Status of the Treatment of Appendicitis, and Dr. Philip B. Callier will read a paper entitled Notes on Dr. Philip B. Collier will read a paper entitled Notes on the International Tuberculosis Congress.

The Medical Society of the Borough of the Bronx.—
At a stated meeting of this society, which was held on Wednesday evening, October 14th, the following papers were read: The Diagnosis and Treatment of Gastric and Duodenal Ulcers, by Dr. N. B. Van Etten; The Surgical Aspect of Gastric and Duodenal Ulcers, by Dr. Parker

Syms.

The International Tuberculosis Exhibit.—Arrangements have been made to have this exhibit brought to New ments have been made to have the efforts of Dr. Alfred Meyer, of 785 Madison Avenue, that the money necessary to carry out the plan was raised. Of the \$30,000 required, the city appropriated \$20,000, and the rest was obtained by private

Charitable Bequests .- By the will of George A. Cotton, the Samaritan Hospital, of Philadelphia, receives \$5.000 ton, the Samaritan Hospital, of Philadelphia, receives \$5,000 for the establishment of the Emma C. B. Cotton free bed. The Pennsylvania Asylum for Indigent Widows and Single Women, of Philadelphia, the Odd Fellows Home for Orphans, of Philadelphia, the Home for Aged and Indigent Odd Fellows, of Philadelphia, the Children's Seaside Home, of Atlantic City, and the Children's Country Week Association, of Philadelphia, receive \$5,000 each. The Masonic Home of Pennsylvania and the William L. Elkins Orphanage for Girls, of Philadelphia, are residuary legatees.

The Eastern Medical Society of the City of New York has made arrangements for a dinner and reception to be held at the Hotel Astor on the evening of Thanksgiving Day, November 26th. This society has an active member ship of over five hundred, and it is hoped that by this social gathering better fraternal relations will be promoted among the members

The Tri-County Medical Society of South Jersey, which is composed of physicians living in the counties of Gloucester, Salem, and Cumberland, will meet in annual session on Tuesday, October 27th, at 1:30 p. m., in Woodbury, N. J. Dr. George Evans Reading, the secretary of the society, announces that a full attendance of members

is desired at this meeting.

Denver Physicians Accused of Failing to Report Infectious Diseases.—It is reported that as a result of an investigation being made by the local health authorities into the typhoid fever conditions prevailing in Denver, warrants have been issued for sixty physicians, who are charged with failing to make proper reports of typhoid fever and other infectious diseases.

Contagious Diseases in Chicago.-During the week ending October 3, 1908, there were 333 cases of contagious diseases reported to the Department of Health, as follows: Diphtheria, 100 cases; scarlet fever, 57 cases; measles, 12 cases; chickenpox, 7 cases; pneumonia, 15 cases; typhoid fever, 100 cases; whooping cough, 20 cases; tuberculosis, 19

ses; diseases of minor importance, 3 cases.

Philadelphia County Medical Society.—The Central Branch of this society held a meeting on Wednesday evening, October 14th. Dr. Achilles Rose, of New York, read a paper on Atonia Gastrica, and demonstrated a special method of treatment. Dr. T. Turner Thomas read a paper entitled Habitual or Recurrent Dislocation of the Shoulder, and reported a successful operation, exhibiting the patient.

The New York Obstetrical Society .-- At the regular The New York Obstetrical Society.—At the regular meeting of this society, held on Tuesday evening. October 13th, the following officers were elected for the ensuing year: President, Dr. J. Clifton Edgar; first vice-president, Dr. William S. Stone; second vice-president, Dr. Joseph Brettauer; recording secretary, Dr. Howard C. Taylor; corresponding secretary, Dr. Robert L. Dickinson; treasurer, Dr. J. Lee Morrill; editor of transactions. Dr. Brooks H. Wells; pathologist, Dr. Franklin A. Dorman.

Sir Arthur Vernon Macan, M. B., died in Dublin on Saturday, October 2d, 2st the age of sixtynfays wears. He

Saturday, October 3d, at the age of sixty-five years. He was one of the best known Irish physicians, and his fame as a gynacologist was well known outside of his own country. He was a Fellow of the Royal College of Physicians of Ireland, and was at one time president of that body. During his presidency of the college he was knighted by the King. For many years he filled with distinction the position of King's Professor of Midwifery in Trinity College, Dublin, and both as an author and as a lecturer was held high esteem.

Vital Statistics of New York.—During the week ending October 3, 1908, there were reported to the Department of Health of the City of New York 1,200 deaths from all causes, of which 633 were in Manhattan, 104 in the Bronx, 385 in Brooklyn, 50 in Queens, and 28 in Richmond. The annual death rate in 1,000 of population was 14.40 in Man-Administration of the Bronx, 13.45 in Brooklyn, 11.22 in Queens, 19.05 in Richmond, and 14.15 in the whole city. The total infant mortality was 385; 311 under one year of age, and 74 between one and two years of age. There were 121 still births. Five hundred and sixty-nine marriages and 323 highs were recorted during the week.

2,423 births were reported during the week.

Report of the Committee of the Neurological Society on Dr. Denslow's Paper on Locomotor Ataxia.— The committee appointed by the president of the New York Neurological Society to report upon the circumstances attending the reading of a recent paper on locomotor ataxia before the New York Academy of Medicine have submitted the following report: "Your committee expresses disapproval of the occurrences following the reading of Dr. Denslow paper. It is the belief of your committee that papers which express radical views should be freely discussed at the time of their presentation, and that every effort should be made to prevent the publication in the newspapers of communica-tions which set forth promise of the cure of diseases which are generally held to be incurable. Your committee further believes that before such cures are exploited they should be submitted to the most rigid investigation.

The Health of Pittsburgh.-During the week ending September 12, 1908, the following cases of transmissible diseases were reported to the Bureau of Health of Pittsburgh: Chickenpox, I case, o deaths; typhoid fever, 29 cases, 8 deaths; scarlet fever, 18 cases, I death; diphtheria, 23 cases, I death; measles, 9 cases, 0 deaths; whooping cough, 2 cases, 0 deaths; pulmonary tuberculosis, 26 cases, 17 deaths. The total deaths for the week numbered 186 in an estimated population of 565,000, corresponding to an annual death rate of 17.06 in 1,000 of population. During June there were 597 deaths, corresponding to an annual death rate of 12.68 in 1,000 of population.

Buffalo Academy of Medicine.—A meeting of the Section in Surgery will be held on Tuesday evening, October 20th. The programme will consist of a "symposium" on gonorrhœa, and papers on the subject will be presented as follows: Morphology of the Gonococcus with its Differentiation by Staining from Other Urethral Bacteria, by Dr. A. A. Thibaudeau; The Treatment of Acute Gonorrhead Urethritis in the Male, by Dr. David E. Wheeler; The Treatment of Chronic Gonorrheal Urethritis and its Complications in the Male, by Dr. Nelson W. Wilson; The Treatment of Gonorrhœa in the Female, by Dr. Earl P. Lothrop; Prophylaxis of Gonorrhœa, by Dr. James A.

Tuberculosis Prizes Awarded.—The awards of the prizes to the exhibitors at the Sixth International Congress on Tuberculosis recently held in Washington, D. C., have been announced. The cash prizes were awarded as follows:
To the Woman's National Health Association of Ireland,
\$500; New York Charity Organization Society, \$500;
White Haven, Pa., Sanatorium, \$500; the Brompton, England Jand, Hospital Sanatorium, \$500; the Henry Phips Dispensary, Baltimore, \$1,000; the Brompton, England, Hospital, \$1,000; the Pennsylvania Society for the Prevention of Tuberculosis, \$100; the Verein Bekampfung der Schweinschucht, \$100. In addition to the cash prizes numerous gold and silver medals were awarded.

Infectious Diseases in New York:

We are indebted to the Bureau of Records of the De partment of Health for the following statement of new cases and deaths reported for the two weeks ending October

The Medical Association of the Greater City of New York.—A stated meeting of this association will be held in Du Bois Hall, New York Academy of Medicine, on Monday, October 19th, at 8:30 p. m. Neurasthenia and Its Treatment is the subject selected for consideration.. Dr. Edward D. Fisher will read a paper on the Ætiology, Pathology, and Course of Neurasthenia. Dr. A. D. Rockrathology, and course of Neurastnema. Dr. A. D. Rock-well will read a paper on True Neurasthenia; its Nature and Treatment. Dr. Sinclair Tousey will read a paper dealing with the treatment of neurasthenia by high frequency currents and the ultraviolet ray, and the treatment of the disease by static electricity will be the subject of a paper by Dr. John Herman Branth. Among those who will take part in the discussions are Dr. George W. Jacoby, Dr. W. M. Leszynsky, Dr. Joseph A. Kene, Dr. Arthur C. Brush, Dr. W. B. Pritchard, and Dr. Joseph Fraenkel.

Brush, Dr. W. B. Pritchard, and Dr. Joseph Fraenkel.

Queens-Nassau Medical Society.—A special scientific meeting of this society was held at the Nassau County Court House, Mineola, on Saturday afternoon, October 10th. Physicians of both counties were present. A very interesting and valuable paper was presented by Dr. John A. Bodine, of the New York Polyclinic, on The Scope of Local Anresthesia in Surgery, in which Dr. Bodine advocated a much larger use of local anæsthesia than was usual. Dr. A. Bassler, of New York, read a paper entitled The Farly Diagnosis of Gastric Carcinoma and showed the im-Early Diagnosis of Gastric Carcinoma, and showed the importance of attention to objective symptoms which might be discovered before any subjective symptoms were present The attendance at the meeting was less than expected, and the character of the papers was such that those who were not present missed much. The regular semiannual meeting of the society will be held in Jamaica in November.

The Mortality of Chicago.-During the week ending October 3, 1908, there were reported to the Department of Health of the City of Chicago 518 deaths from all causes, as compared with 583 for the preceding week, and 565 for the corresponding period in 1907. The annual death rate in 1,000 of population was 12.47. Of the total number of deaths 126 were of children under five years of age, 60 of deaths 120 were of children under five years of age, 50 of children between one and five, 35 of persons between five and twenty years of age, 105 between twenty and sixty years of age, and 102 over sixty years of age. The princicipal causes of death were: Apoplexy, 12 deaths; Bright's disease, 30 deaths; bronchitis, 10 deaths; consumption, 57 deaths; cancer, 27 deaths; diptheria, 10 deaths; heart diseases, 41 deaths; intestinal diseases, acute, 112 deaths; measles, 11 death; persons diseases, 12 deaths; neurons deaths; n measles, I death; nervous diseases, I3 deaths; pneumonia, 4I deaths; scarlet fever, 7 deaths; suicide, II deaths; typhoid fever, 18 deaths; violence (other than suicide), 35 deaths; all other causes, 99 deaths.

Scientific Society Meetings in Philadelphia for the Week Ending October 24, 1908:

Monny, October 10th Medical Jurisprudence Society;
Northeast Branch, Philadelphia County Medical

Society.

Tuesday, October 20th.—Dermatological Society; Academy of Natural Sciences; North Branch, Philadelphia County Medical Society.

Wednesday, October 21st.—Philadelphia County Medical Society (business meeting open to members only); Section in Otology and Laryngology, College of Physicians; Association of Control Franklin Institute Association of Clinical Assistants, Wills Hos-

THURSDAY, October 22d.—Pathological Society; Entomological Section, Academy of Natural Sciences; Section Meeting, Franklin Institute.

FRIDAY, October 23d.—South Branch, Philadelphia County Medical Society; Northern Medical Association; Philadelphia Neurological Societ

delphia Neurological Society. The Connecticut River Valley Medical Society met recently at Northfield, Mass. Dr. F. J. Canedy, of Shelbourne Falls, Mass., presided at the morning session. and Dr. E. R. Campbell, of Bellows Falls, Vt., occupied the chair during the afternoon session. The programme included the following papers: Pseudoangina Pectoris, by Dr. George G. Sears, associate professor of clinical medicine, Harvard Medical School; Cancer in and about the Mouth, by Dr. Harry Homer Germain, associate professor of surgery, Tufts Medical School; Pericarditis and its Treatment, by Dr. Hermon F. Vickery, instructor in clinical medicine, Harvard Medical School; A Consideration of some of the points most commonly met with in the Study and Treatment of the so called Rheumatoid Diseases, by Dr. Joel E. Goldthwaite, instructor in orthopædies, Harvard Medical School; Some Aspects of Psychotherapy, by Dr. John Jenks Thomas, assistant professor of neurology, Tufts Medical School; Some of the Newer Practical Things which have come out of the Laboratory, by Dr. Timothy Leary, professor of pathology and bacteriology, Tufts Medical

The Health of the Canal Zone.—During July the Sanitary Department of the Isthmian Canal Commission reported 5 deaths from typhoid fever, 12 from æstivoautunnal malaria, 41 from clinical malaria, 3 from hæmoglobinuric fever, 2 from diphtheria and croup, 1 from international control of the co fluenza, I from amœbic dysentery, 12 from clinical dysentery, 2 from beriberi, 6 from purulent infection and septicæmia, 21 from tuberculosis of the lungs, 2 from general tuberculosis, 3 from syphilis, 4 from cancer, 1 from cerebrospinal meningitis, 3 from tetanus, 15 from pneumonia, 5 from bronchopneumonia, 25 from diarrhœa and enteritis, under two years of age, 1 from puerperal septicæmia. The total deaths numbered 295, in a population of 121,607, corresponding to an annual death rate of 29.11 in 1,000 of popu-The death rate among the white employees was 12.69, among the black employees 15.43; among all the employees of the Canal Commission, excluding the civil population, the death rate was 14.68 in 1,000. The morbidity rate was 2,01 in 1,000 employees. Four hundred and forty-three pounds of quinine were issued during the month. The chief branch of sanitary work in the city of Panama is that which aims to prevent the propagation of plague should it be once introduced into that city. To that end the killing of rats is carried on by every known method with some degree of success. The advent of a few cases of rabies caused a campaign of extermination of stray dogs, so that during the month 337 such animals were killed.

Society Meetings for the Coming Week:

MONDAY, October 10th.—New York Academy of Medicine (Section in Ophthalmology); Medical Association of the Greater City of New York; Hartford, Conn., Medical Society.

Tuesday, October 20th.—New York Academy of Medicine (Section in Medicine); Buffalo Academy of Medicine (Section in Pathology); Tri-Professional Medical Society of New York; Medical Society of the County of Kings, N. Y.; Binghamton, N. Y., Academy of Medicine; Clinical Society of the Elizabeth, N. J., General Hospital; Syracuse, N. Y., Academy of Medicine; Ogdensburgh, N. Y., Medical Association.
Wednesday, October 21st.—New York Academy of Medicine (Section in Genitourinary Diseases); New York Society of Dermatology and Genitourinary Surgery: Woman's Medical Association of New York City (New York Academy of Medicine); Medicolegal Society, New York; New Jersey Academy of Medicine (Jersey TUESDAY, October 20th.-New York Academy of Medicine

New York; New Jersey Academy of Medicine (Jersey City); Buffalo Medical Club; New Haven, Conn., Medical Association; New York Society of Internal Medicine; Northwestern Medical and Surgical Society of New York.

THURSDAY, October 22d .- New York Academy of Medicine (Section in Obstetrics and Gynæcology); Brooklyn Pathological Society; Hospital Graduates Club, New York; New York Celtic Society.

Friday, October 23d—Academy of Pathological Science, New York; New York Society of German Physicians:

New York, New York Society of German Physicians: New York Clinical Society. SATURDAY, October 24th.—West End Medical Society, New York; New York Medical and Surgical Society; Har-vard Medical Society, New York: Lenox Medical and Surgical Society, New York.

Meetings of Sections of the New York Academy of Medicine.—The Section in Ophthalmology will hold a clinical meeting on Monday evening, October 19th. After the presentation of a number of interesting cases by Dr. R. G. Reese, Dr. J. R. Shannon, and Dr. E. L. Oatman, Dr. J. Herbert Claiborne will read the paper of the evening on Acute Retrobulbar Optic Neuritis, which will be followed by a general discussion.

The Section in Medicine will meet on Tuesday evening, Cotober 20th. Dr. H. S. Patterson will demonstrate the reaction to Moro's tuberculin salve. Dr. Wilhelm Falta, of Professor Van Noorden's Clinic, Vienna, will read a paper entitled The Relation of the Internal Secretions to Diabetes Mellitus. Among those who will take part in the discussion are Dr. S. J. Meltzer, Dr. James Ewing, and Dr.

Graham Lusk.

The Section in Genitourinary Surgery will hold a meeting on Wednesday evening, October 21st. wood will present a specimen of tuberculous kidney; Dr H. H. Vineberg will present a specimen of encysted calculus from a female bladder; and Dr. Martin W. Ware will present a specimen of encysted calculus from a male bladder. Dr. Ellice McDonald will read a paper entitled Bladder Lesions following Pelvic Operations upon Women, including the report of ten cases. Dr. Leo Buerger will demonstrate, by request, a new irrigating indirect observation and deable, westered exthatorizing explosions a metal-al-indouble ureteral catheterizing cystoscope embodied in a single instrument.

single instrument. The Section in Obstetrics and Gynaecology will meet on Thursday evening, October 22d. Dr. Abram Brothers will present a report of the removal of two hundred and five gallstones simultaneously with operation on cervix uteriand adnexa. Dr. Sidney S. Graber will read a paper on Vaginal Fixation, and a paper on Pollakuri in Women will be read by Dr. Harry S. Furniss.

Medical Society of the State of New York.—The First District Branch of the Medical Society of the State of New District Branch of the Medical Society of the State of New York, comprising the counties of Dutchess, New York, Orange, Putnam, Rockland, and Westchester, will hold its second annual meeting on Wednesday, October 21st, at the Yassar Brothers Institute, Poughkeepsie, N. Y. The first session will be held at 10 a. m. After the transaction of routine business, which will include the election of officers, the following papers will be read: A Successful Demonstration of the Problem of Obtaining Sterile Cow's Milk, by Dr. John T. Howell, of Newburgh; A Campaign against Tuberculosis, by Dr. S. E. Getty, of Yonkers; Some Observations on the Expert in Insanity upon the Witness Observations on the Expert in Insanity upon the Witness Stand and Some Causes of Insanity by Dr H Fruest

Schmidt, of White Plains; The Control of Ophthalmia Neonatorum, by Dr. John T. Wheeler, of Chatham; Anterior Poliomyelitis, by Dr. M. W. Barnum, of Ossining; The Sequlæ of Peritonitis and Postoperative Sequlæ, by Dr. Joseph Price, of Philadelphia. At the afternoon session which receives the Challed Price. Dr. Joseph Price, of Philadelphia. At the afternoon session, which meets at 2 o'clock, the programme includes the following papers: Some Nose, Throat, and Ear Symptoms of Significant Interest in General Practice, by Dr. D. S. Dougherty, of New York; The Prevention and Preoperative Treatment of Mastoiditis, by Dr. W. Sohier Bryant, of New York; The Need for the Correction of Errors of Refraction in Children, by Dr. Frank Van Fleet, of New York; The Detection and Treatment of Abnormal Blood Pressure, by Dr. Louis F. Bishop, of New York; The Prognosis and Treatment of Abnormal Blood Pressure, by Dr. Ezbert Le Fevre, of New York; The Senile Heart, by Dr. Egbert Le Fevre, of New York; The Senile Heart, by Dr. L. C. Wood, of Poughkeepsie. In the evening the annual banquet of the Medical Society of the County of Dutchess will be held at the Nelson House. Dr. S. W. S. Toms, of Nyack, is president of the society, Dr. C. E. Denison, of New York, is secretary, and Dr. N. F. Curtis. of White Plains, is treasurer.

The Sixteenth International Medical Congress.-Ar rangements are being made for this meeting, which is to be held in Budapest, August 29 to September 4, 1909, and the committee wishes to remind the medical profession that contributions to the congress must be announced to the sec contributions to the congress must be announced to the secretary before January I, 1909. Manuscripts should be in the hands of the committee by January 31, 1909. Attention is also called to the fact that the time allowed for the reading of a paper is not more than twenty minutes. The request is made that manuscripts be clearly written, as the proofs are to be corrected at the office of the general secretary. Copies of manuscripts will be returned by July 31, 1909. The general secretary of the congress is Professor Emil Grosz, M. D., Budapest, VIII., Esterhazy-utcza 7. Emil Grosz, M. D., Budapest, VIII., Esterhazy-utcza 7. Blank forms of application for membership to the congress and for the presentation of papers can be obtained from the chairman of the American committee, Dr. J. H. Musser. 1927 Chestnut Street, Philadelphia. The American committee is composed of the following members: Dr. John H. Musser, of Philadelphia, chairman; Dr. Herbert L. Burrell, of Boston, president of the American Medical Association; Colonel W. M. Gorgas, United States Army, president elect of the American Medical Association; Dr. Robert M. O'Reilly, Surgeon General of the United States Army; Admiral P. M. Rixey, Surgeon General of the United States Public Health and Marine Hospital Service; Dr. Frederick Forchheimer, of Cincinnati; Dr. George H. Simmons, of Chicago; Dr. Richard Mills Pearce, of New York; Dr. Reginald H. Fitz, of Boston; Dr. R. Matas, of New Orleans; Dr. William H. Welch, of Baltimore; Dr. F. Fremont Smith, of Washington, D. C.; Dr. John A. Witherspoon, of Nashville; Dr. C. H. Frazier, of Baltimore: Dr. F. Fremont Smith, of washington, Dr. C.; Dr. John A. Witherspoon, of Nashville; Dr. C. H. Frazier, of Philadelphia; Dr. E. G. Janeway, of New York; Dr. George M. Kober, of Washington, D. C.; Dr. Ramon Gui teras, of New York; Dr. Grover W. Wende, of Buffalo: Dr. Howard A. Kelly, of Baltimore; Dr. Arthur D. Bevan, Ch. Chicago, Dr. Stockton, of Ruffalo: Dr. teras, of New York; Dr. Grover W. Wende, of Buffalo: Dr. Howard A. Kelly, of Baltimore; Dr. Arthur D. Tumors of Adrenal Origin, with Particular Reference

to Hypernephroma of the Kidney,
By Herbert C. Moffitt.
The Relation of Carcinoma of the Corpus Uteri to
Fibroids,
Fracture of Lower Epiphysis of the Tibia,
By Frederic S. Coollinge.

1. Hypernephroma of the Kidney.-Moffitt gives the following most important points in diagnosis of hypernephroma: I. Hæmaturia is a common symptom and may often be the first. There may be long intervals between attacks of bleeding, or recurrences every few days or weeks. Pain is frequently an accompaniment, and may be exactly that of renal colic, or the bleeding may be painless, without cause and only noticed by accident. The physician should regard every hæmaturia with suspicion, and try all means to discover the cause; only in this way can mistakes be avoided. The bleeding may be only a few drops, or profuse and deadly. 2. Pain may also be an early symptom. Like hæmorrhage it may long precede other symptoms or sepsis. Severe pain may accompany hæmaturia, or may be due to hæmorrhages into the tumor, or even to congestion. The pain may be local, and is then of great value in determining the affected side, or it may be referred to the epigastrium or to the sacrum; it may radiate in the distribution of the lumbar or sacral plexus, or it may be referred to distant parts. 3. The tumor may vary greatly in size and rapidity of growth. It may be present for years without giving trouble, and may suddenly assume a malignant character. 4. Metastases and their peculiarities have frequently been referred to. They are most often found in the lungs, liver, and bones. The peculiarities of bone metastases in adrenal tumors in childhood have already been illustrated. Pulsating bone tumors should arouse suspicion of metastases from either adrenal or thyreoid. 5. Pigmentation has been observed in but few cases of hypernephromata. 6. Trophic changes. Abnormal development of genitalia or of general overgrowth associated with tumors of the adrenals in childhood may be found. Hypertrichosis has been observed in both children and adults. 7. The urine may be normal throughout years despite the presence of a renal tumor. A few red cells may appear after manipulation of the tumor, or may persist during the interval between attacks of hæmaturia. Albumin may be caused by inflammatory changes in the neighborhood of the tumor or may be due to transudation from tumor masses projecting into the renal

2. The Relation of Carcinoma of the Corpus Uteri to Fibroids.—Williams concludes that there is a distinct relationship between carcinoma of the corpus uteri and fibromyomata, and that this relationship probably lies in certain common etiological conditions. The predisposition of fibroids to become complicated with cancer does not constitute an indication for their routine removal as soon as discovered, providing the patient can be kept under close observation, but any marked increase in the loss of blood from a fibroid, or the appearance of any vaginal discharge in the intervals between the hæmorrhages should be regarded as suggestive of the development of carcinoma. In a fibroid where either of these symptoms is present an immediate curettage should be performed in order that the condition of the endometrium may be examined, even if a radical operation has been decided upon. Every uterus removed for fibroids should be immediately opened by an assistant and the endometrium inspected to guard against possible oversight of a malignant process. In all cases of fibroids complicated by adenocarcinoma of the corpus a complete removal of the uterus including the cervix is the

10. Perithelial Sarcoma of the Uterus, By W. A. NEWMAN DORLAND.

3. The Treatment of Strictures of the Nasal Duct with Lead Styles .- Moulton says that in selecting styles instead of cannulæ for permanent dilatation, one is influenced by the fact that experience has proved that cannulæ quickly become clogged with mucus and pus, becoming sources of infection, and at the same time, ceasing to act as drains. This can not be avoided, even by almost daily removal and cleansing, which process is even more irksome to both patient and surgeon than probing. Experience, on the other hand, proves that with a style properly inserted, secretions do not accumulate, the tears readily find their way along the sides of the style into the nose, and the patient need not be seen oftener than once a month. The reasons for preferring lead as the material out of which to make the styles are: (1) It is a pliable material; (2) it is easily cut, smoothed, and adapted to each individual case by the surgeon himself; (3) it is comfortable to the patient; (4) it is not acted on by the secretions: (5) it is cheap and easily obtained. On the other hand the other materials available are all objectionable. Aluminum soon becomes corroded, silver also, in time. While this objection does not apply to gold, yet gold is expensive and hard to adjust on account of its rigidity. The proper preparation and placing of the styles are essential to success, and close attention must be paid to this important, if simple, technique. After the canaliculus has been cut and the duct dilated, at one sitting or several, to Bowman's No. 5, or even to No. 8, if possible, the depth of the duct is measured on the probe, and a piece of lead wire is cut

to the corresponding length, taking off about one eighth of an inch from the lower end to prevent it from resting on the floor of the nose and allowing from one fourth to three eighths of an inch extra length on the upper end to be bent over at a little more than a right angle to prevent its slipping down out of reach. The main shaft of the style should be curved to fit the canal, as determined by the bend of the probe which has been passed. The shoulder or upper end should have a curve slightly down and forward so that it will lie in the slit canaliculus, out of view and without tension. The tip of this upper end must not turn backward toward the eyeball. If it does it will cause trouble by touching the eyeball or by compressing the tissues of the eyelid between it and the eyeball. There should be no tension. If the end sticks up a little, it may be bent down without withdrawing the style. The style will partly adapt itself to the canal owing to its flexibility, but if the fit is not good, it must be withdrawn, remolded, and reinserted till it occupies the proper position without tension.

6. Fallacious Standards Employed in Artificial Infant Feeding.—Pisek speaks of the so called standards that are applied in artificial infant feeding. He says that it is an accepted standard that Nature should be followed. What is following Nature? Some say one thing and some another. The simplest standard heard of is, give the infant milk. If its mother's milk fails, give it cow's milk, goat's milk, or ass's milk, but follow Nature and give milk. The next advanced standard is that all milks are composed of the same ingredients, but in different proportions, and changing the percentage composition will practically convert the milk of one kind of animal into that of another. Another standard is that human milk is composed of fats, carbohydrates, proteids, mineral matter, and water, and the infant's food should contain these ingredients in the same proportions. A favorite standard has been that cow's milk was acid and human milk alkaline, and therefore five per cent. of lime water should be added to cow's milk to give it the same reaction. A newer standard is that the difference between human milk and cow's milk is due to the fact that they contain casein or caseinogen and lactalbumin in different quantities and relative proportions, and that these relative proportions are definite for each milk. It is a widely accepted standard that human milk is sterile and cow's milk contains bacteria, and therefore the cow's milk should be sterilized or pasteurized before being given to infants. Another standard is that of gain in weight of the infant caused by a given food. A recent standard is that the infant needs food that will produce a certain number of calories, depending on the size of the infant. The standard that human milk is composed of fats, carbohydrates, proteids, mineral matter, and water, and that the infant's food should contain these ingredients in the same proportions, is too broad, as under it any form of food could be emploved, meat, vegetables, bread, etc., as all of these foods contain fat, carbohydrates, proteids, mineral matter, and water. This standard merely states that the infant's food should contain the elementary food substances without which life could not be maintained. The standard that as human milk is alka-

line and cow's milk acid, five per cent. of lime water should be added to cow's milk for infants, fails in practice, for five and ten per cent. of lime water is recommended to be added to diluted milk, which oftentimes makes the amount added to the whole milk 100 per cent. or more. Lime water or other alkali has a specific action on the milk, altering or preventing its curding in the stomach by rennet or pepsin. The practice may be very good, but the standard is worthless and masks the true purpose and value of lime water in infant feeding. The standard that was brought forward after the weakness of many of the previous standards was recognized, viz., that it was the relative proportions of casein or caseinogen and lactalbumin that made the difference between milks of different species, is not undisputed. In the first place, casein or caseinogen does not seem to be the same for each kind of milk, and then, there is no constant ratio between casein and lactalbumin in cow's milk as was supposed. The quickest and surest way to satisfy oneself as to whether the caseins in human milk and cow's milk are the same is to add rennet and a very small quantity of dilute acid to specimens of human milk and cow's milk and note the resulting curds. The standard that as human milk is sterile and cow's milk contains bacteria, cow's milk used for infants should be sterilized by heating, cannot be maintained, for we know of the use of buttermilk made by adding lactic bacteria to milk, and it is lauded as a remedy for intestinal disorders for which sterilized milk was thought to be ideal at one time; and even giving bacteria to infants has been reported as successful. That the food must not contain bacteria is a standard that evidently cannot be maintained.

7. The Gospel of Top Milk .- Jacobi states that artificial food is not equivalent to woman's milk. Cow's milk cannot be changed into woman's milk. The efficiency of alleged improvements in artificial feeding is liable to be overestimated and not always received with sound criticism. The advice to add cow's milk fat to cow's milk in order to make it more nutritious or to make its casein more digestible, is dangerous. Between the fats of the woman's and of the cow's milk there are essential physical and chemical differences. The danger of overfeeding with fat can be obviated by reducing its proportion in milk mixtures to two or two and one half per cent. Cereal decoctions improve the nutrient value and the digestibility of a milk mixture. If ever the baby, while feeding well, does not increase in weight, the intelligent practitioner may be obliged to add carefully and slowly to the caloric value or general nutritiousness of the food mixture by increasing either the cereal decoction or the fat percentage. Feeding cannot be regulated by mathematics so well as by brains and by the wants of the individual baby. The top milk gospel is a heresy.

with Hypodermic Injections of Iron,

By LEROY S. PETERS. 2. The Present Status of the Radical Mastoid

Operation for the Cure of Chronic Purulent Otitis Media.-Phillips remarks that the radical operation is indicated: 1, When a permanent cessation of the purulent process has not been effected by prolonged local intratympanic treatment, combined if necessary with such minor operation as removal of granulations, enlarging perforation, etc. When the cure has not been effected by the removal of necrosed ossicles and the curettage of the middle ear. 3, When acute symptoms of mastoiditis are present. 4, When a sudden cessation of the pus discharge produces vertigo, pain, or other unusual symptoms. 5, The appearance of facial paralysis during the course of chronic purulent otitis media. 6, Attacks of vertigo, indicating that the necrotic process involves the labyrinth. 7, In all cases where intracranial or lateral sinus involvement has already appeared. 8, Where there are positive symptoms of cholesteatoma in the mastoid antrum. 9, Where there are fistulous openings in the cortex of the mastoid process or in the osseous canal wall. 10, Whenever extreme depression or other symptoms of disturbed mentality accompany the disease. The operation is contraindicated: I, When the purulent process is tuberculous and accompanied by advanced general tuberculosis. 2, In advanced pernicious anæmia or albuminuria and in cachectic diabetes. 3, It is usually contraindicated in young children. 4, In all cases where the disease is confined to the ossicles and tympanic cavity. 5, In adults who have scanty otorrhœa without odor, with improper opening of the drum membrane, behind which are retained masses of secretion. 6, In all cases where it is possible to effect a cure by any of the other methods described. It will be thus seen that the percentage of cases which should be subjected to the radical operation is not large. It is also true that during the past five years too little discrimination has been employed in the selection of suitable cases for the operation. This should in no wise lead us to belittle this most important surgical procedure, for when properly performed in severe and dangerous cases of chronic otitis media it is the only safe and life saving procedure known to surgery. His reasons for advising against performing the radical operation in young children are: 1, The disease is rarely of sufficient extent to require it. 2, The disease usually yields to local treatment providing diseased adenoids and tonsils are removed. 3, By establishing free drainage, through a large perforation, with well maintained local treatment, a cure usually results. 4, It is better to place reliance upon these measures, aided by the marvelous recuperative powers of youth, than partially or wholly to destroy his functions of hearing with all its train of misfortunes to happiness, education, the enjoyment of sounds, musical and otherwise, and finally to gaining a livelihood. He has always opposed performing double radical op-

crations in children except to save life.

4. A Contribution to the Study of the Diathetic States.-Nesbitt says that every civilized individual has inherited some depraved nutritional tendencies. The majority are so profoundly affected that the stress of modern life, together with the effects of infection, dissipation, and injury, make their premature destruction inevitable. If it is possible to correct these nutritional faults while the individual is in the formative period, it is the plain duty of every physician to study the heredity of every child in his clientèle, and to see that each has the best opportunity to attain his highest usefulness and greatest longevity. The author has collected forty-seven cases of cancer, sixteen patients having cancerous progenitors; thirty-five cases of chronic nephritis, fourteen patients inheriting the tendency to nephritic disease from direct progenitors; thirty-eight cases of diabetes mellitus, thirteen patients having diabetic heredity. He concludes that the development of malignant neoplasms is furthered, if not caused, by the admixture of the two diathetic states in procreation. The prepon-derance of scrofulosis in the diathetic history is probably essential to the production of cancer. The great majority of cancerous individuals are the result of procreation by two, one of whom is arthritic and the other scrofulous. Transmission of diatheses is most often from father to daughter, and from mother to son, as has been determined with reference to other hereditary transmission. Preponderance of arthritism over scrofulosis in the ancestry of an individual is a possible factor in the production of renal cancer, when the individual has had a cancerous ancestor. Intensification of the arthritic diathesis through hereditary transmission is the most probable predisposing cause of chronic progressive renal degeneration. Alcoholism in the ancestral and personal history of the individuals who are essentially arthritic is the most important precipitating cause of chronic nephritis. It is possible that alcoholism and renal disease combined in the heredity of an individual predispose to the parenchymatous type of nephritis. The other ætiological factors recognized in the production of chronic nephritis are secondary in importance, and contribute in a general way only to the development of the disease. Scrofulosis is important in the ætiology of nephritis as a remotely contributing factor. Diabetes mellitus is possibly the result of the transmission of the arthritic diathesis through several generations in which there has been little or no marital admixture of scrofulosis. Scrofulosis is unimportant in the ætiology of this disease. The production of diabetes mellitus in the majority of instances depends upon the further development of nutritional fault that has been inherited.

4. Vaccine Therapy.—Crofton states that the routine estimation of the opsonic index in the treatment of localized infections is practically an impossibility for the busy practitioner. But there are a large number of cases of strictly localized infections, such as acne, sycosis, lupus, etc., which may be safely treated without reference to this. writer holds that opsonin and complement are probably identical, and that permanent immunity is conferred by a heat stable body of the nature of immune body, which fixes the complement on to the microbe. He always begins with a very small dose of vaccine, the succeeding doses being largely increased at each vaccination, and a final large dose being given after the patient is apparently cured. This last has a potent influence in preventing relapse. Vaccine therapy may also be of use as a prophylactic measure. If the children of tuberculous parents were given a few increasing doses of tuberculin when infants it would eliminate their tuberculous tendency.

18. Infantile Paralysis.—Tubby discusses the surgical treatment of infantile paralysis due to anterior poliomyelitis. He recognizes four stages in the disease: I. The stage of onset, when the first symptoms of paralysis appear. 2. The period of quiescence, lasting from one to four weeks: deformity now commences in the affected areas. 3. The stage of partial recovery, lasting one to six months, due to the gradual absorption of the œdema and inflammatory exudation. 4. The chronic stage, lasting for an indefinite time. Suitable measures of treatment during (2) the quiescent period and (3) the stage of partial recovery, are dry warmth to the affected parts, massage, electricity, prevention of deformity, and the functional use in a normal direction of those muscles which are recovering. The object of all these forms of treatment is to ensure that the ultimate amount of muscular power retained or regained should be as great as possible. These objects can be effected: I. By the maintenance of the nutrition of the muscles. 2. By retaining the limb in a normal position, and guarding against the stretching of ligaments, muscles and tendons of the paralyzed parts. 3. By preventing contraction of healthy unopposed or partially unopposed muscles. The means of surgical treatment are as follows: I. Mechanical. The simpler the apparatus the better. 2. Tenotomy. This is of some value in helping to overcome contraction and in permitting relaxation. 3. Arthrodesis, or artificial joint fixation is done when no further recovery can be expected in the paralyzed muscles. Success is rare in children under ten years of age. The ankle is the joint usually operated upon. 4. Tendon and muscle transplantation. The indications here are: (a) To replace or reinforce completely or partially paralyzed muscles or groups of muscles. (b) To subtract from the power of muscles which are too strong and to add to those which are too weak. (d) To alter the direction of perverted tendon action. (e) As a supplementary measure to arthrodesis. The causes of failure are improper selection of cases, insufficient preliminary correction of secondary deformities, attempting to use weak muscles as reinforcers, defective asepsis, insufficient freeing and bending of tendons, insufficient fixation or early adhesion of tendons, and expecting transplanted tendons to control loose joints. 5. Nerve anastomosis and nerve grafting make new paths for the passage of impulses, and revivify dormant muscles.

Itching.—Jamieson states that itching, or pruritus, is essentially a surface sensation and is probably located in the epidermis. It is just when an abrasion or a wound is finally cicatrizing that itching, popularly regarded as a favorable sign, makes its appearance. Pressure is inimical to itching. The tormenting itching in scabies is caused

by the female acarus driving her tunnel through the epidermis. Intense itching with entire absence of any definite skin disease is called essential pruritus. Or it may occur in direct association with some accredited lesion or integumentary ailment. It occurs as a superficial manifestation in both. When encountered over or near varicose veins it is the surface innervation which is disturbed. The proximate cause of itching is closely connected with that of urticaria. Unna's theory is that itching is due to a disproportion between the pressure of the tissue juices and that of the limiting corneous layer, and that the relief afforded by scratching is at least partly referable to the escape of serum from lacerations produced by the nails, temporarily equalizing the tension. But this theory does not account for itching where there is no evidence of ædema. We must probably assume in addition wholly to account for the pruritus that there is likewise a condition of hyperæsthesia, an undue sensitiveness of the skin. Generalized pruritus may be set up by parasites. The one skin disease with which itching is most commonly associated is eczema. It is met with in acute erythematous, papular, and scaly eczemata, while it is almost wholly absent in the vesicular and weeping forms. The thinner the epidermis the more pronounced is the itching in chronic infiltrated eczema. Like insects, plants may set up a dermatitis and induce itching. The early eczematous or lichenous eruptions of mycosis fungoides are often accompanied by itching, so intense as to suggest the nature of the trouble, and only yielding to the x rays. Other forms of itching are those due to poisons generated from within, as in severe jaundice and Hodgkin's disease. Pruritus of the anus and of the vulva are also important forms. In all cases of generalized itching the possible existence of scabies or lice, or the chance of the irritation having been started by plants, must ever be borne in mind. Itching cannot be treated solely as a substantive lesion without risk of failure. Medicated soaps are useful where there is no skin disturbance—as in senile pruritus apart from pediculi. In most cases of pure senile pruritus a permanent cure can be obtained by giving a course of subcutaneous pilocarpine injections; one each night for two or three weeks. These usually restore the sweat gland system to functional activity and with the reestablishment of cutaneous exhalation the trouble ceases. Hot water usually gives great relief in the itching of eczema.

3 and 4. Vaccine Therapy.—Matthews discusses the potentialities and limitations of therapeutic inoculation in the treatment of microbic infections, with or without the assistance given by the estimation of the opsonic index. He defines the opsonic index as the expression of the measure of the phagocytic power produced in a sample of washed leucocytes by the serum of the individual in question, as compared with the phagocytic power induced in a similar sample of leucocytes by the serum of one or more healthy individuals. This latter power is taken as unity, and the index of an infected individual is expressed as a fraction of unity, above or below unity, according to the greater or less quantity of protective substances in the infected serum, as compared with the normal serum. The opsonic index then is the measure of

the resisting power, as comprised in phagocytosis, of a serum, against the microbe in question. A vaccine is a killed bacterial culture suspended in sterilized normal saline solution, to which lysol to the strength of 0.25 per cent., or carbolic acid to the strength of 0.5 per cent. has been added. Vaccines are accurately standardized by mixing together definite quantities of vaccine and normal human blood of known corpuscular content. Smears are made of the mixture, are dried, fixed, and stained, and the numbers of red cells and microbes counted in the field. An estimation of the number of microbes in each cubic centimetre of vaccine is then possible. The cultures are killed by immersion for one hour in a water bath at 60° C., and the sterility having been demonstrated by culture methods, a suitable dilution for use is made in rubber capped sterile bottles for laboratory and hospital use, and in sealed glass sterilized capsules, containing slightly more than one cubic centimetre, for general use. The injection of a dose of vaccine into a healthy normal individual produces either: (1) An immediate rise in the protective substances, as indicated by the op-sonic index ("positive phase" of Wright). (2) A fall of longer or shorter duration ("negative phase"), followed by a rise up to or above normal, in its turn followed by a fall toward normal. (3) A fall tending to be more or less permanent according to whether the dose is small, medium, or excessive. In general in the treatment of infections it is desirable to maintain an average high level of resistance. Within certain limits the duration of the effects produced by any one inoculation varies proportionately to the dose of vaccine inoculated—that is, the longer the negative phase the longer the positive phase will be. In any infection which is not strictly localized, and more especially in septicæmias, the curve to be aimed at is one in which no negative phase occurs. The corollary is that the response invoked is short, and therefore reinoculation must quickly follow, even to daily doses. In such cases the opsonic index is of paramount value as a guide. In chronic or acute strictly localized processes, on the other hand, a temporary negative phase, if followed by a prolonged positive phase, will be of no consequence—and the advantage is gained that injections need not be given oftener than once a week. The negative phase should not last longer than twenty-four hours. The production of a permanent negative phase is disastrous except in the case of a localized furuncle, which is maturating very slowly, but in which absorption without suppuration is unlikely to occur. Treatment of individual cases falls under two headings: (1) The isolation of the microbe at fault, and the preparation and standardization of a vaccine; and (2) the estimation of the correct dose and of the period which should elapse between doses. Grant, Campbell, and Anderson report some cases of vaccine therapy in general practice. The cases include tuberculous adenitis, folliculitis barbæ, tuberculosis of the toe joint, and pulmonary tuberculosis. The results in all were satisfactory. The scars resulting were soft and pliable, and the disfigurement slight. Recovery seemed rapid, with a consequent saving of suffering and expense to the patient. The absence of severe surgical measures minimized the risk of a general

tuberculous infection and obviated the risk of general anæsthesia. Although opsonic estimations were only occasionally made they suggested that the index was being steadily raised.

1. Relations between Congenital Muscle Defects, Infantile Nuclear Atrophy, and Dystrophia Muscularis Progressiva Infantilis. - Ziehen reports two cases, one of congenital ophthalmoplegia externa, the other of a total monolateral defect of the pectoralis major associated with a very considerable defect of the pectoralis minor, and with these as a text discusses the nature of such cases. He divides these cases into two groups: A, congenital atrophic paralyses, (a) nuclear, (b) primary, muscle defects; B, acquired atrophic paralyses dependent on a congenital condition, (a) nuclear, infantile progressive bulbar paralysis, (b) primary myopathy dystrophia muscularis progressiva. He believes that these two groups can be distinguished with reasonable certainty, as there is no progressive course in the purely congenital cases.

4. Conjunctival Reaction in Tuberculosis .-Fabian and Knopf conclude that a certain prognostic value cannot be denied the conjunctival reaction. A positive reaction indicates with the greatest probability the presence of tuberculosis, but a negative reaction does not exclude the presence of this disease. They state that their use of the conjunctival reaction was attended with no injury, and that they consider it of a value not to be underestimated.

5. Complement Deviation in Scarlet Fever .-Boas and Hauge declare, from the investigation of sixty-one cases, that the complement deviation obtained by the technique employed by them was so rare in scarlet fever and disappeared so quickly after the disease that it in no way is prejudicial to the great diagnostic value of Wassermann's reaction in syphilis.

3. Extractum Digitalis Depuratum.-Höpffner recommends the use of this preparation because 1, it produces a certain and prompt therapeutical action; 2, the action upon the pulse, affecting its quality, and frequency, and the diuresis appears relatively quickly; 3, it appears to disturb the stomach less than treatment with digitalis leaves given with sufficient energy to produce the same therapeutic result; 4, an energetic digitalis treatment can be carried out more easily with the purified extract than with the inconstant digitalis leaves without equal danger of intoxication through cumulation.

4. Condurango Bark and Kawar Root.-Böhm finds in both the condurango leaves from Ecuador and the kawar root from the Transvaal etherial oils that are very similar in their characteristics. Both plants come from their native places recommended as cures for cancer, both belong to the same family, and the chemical composition of the drugs obtained from each bears an extremely close resemblance.

6. Studies in Phagocytosis.—Bechhold gives as the results of his experiments that: I, sodium hydroxide arrests phagocytosis, but only when the leucocytes are visibly changed. The destructive action of the sodium hydroxide is markedly lessened by the presence of serum and still more by that of the entire blood. 2, Relatively large quantities of lactic acid do not greatly influence the phagocytosis, and even a visible change of the leucocytes by lactic acid does not hinder phagocytosis. 3, Addition of oxygen, whether in the presence of the red blood corpuscles or not, has no influence on phagocytosis. The same can be said of saturation with carbonic acid and with illuminating gas, neither prevent phagocytosis. 4, Experiments with various colloid substances show that the colloid nature itself has no effect upon phagocytosis.

11. Quinine Intoxication.—Salomon reports the following interesting case: A woman had been treated by him several months before with large doses of quinine which she had borne well. On account of recurrence of the disease for which she had been treated she consulted him again and was prescribed the same remedy. Immediately after the first dose of 0.3 gramme she complained of bad vision, ringing in the ears, and vomiting, so that on the following day she was directed to take only half a dose once a day. On the next morning her entire face was swollen and so ædematous that the eyes could scarcely be seen. The margins of the lupus erythematosus, from which she suffered, were covered with thick blood crusts, while the lupus was permeated with numerous little hæmorrhages. There was also extensive purpura hæmorrhagica in parts free from this disease, and a severe hæmorrhage from the conjunctiva of the right eye. She was suffering from dyspnæa, hæmatemesis, bloody diarrhœa, hæmaturia, and bleeding from the mucous membranes of the mouth and nose. Recovery took place after a few days. The points of particular interest are the developed idiosyncrasy, the extraordinary severity of the toxic symptoms from so small a dose, and the limitation of the hæmorrhages in the face to the efflorescences of the lupus erythematosus.

Modern Laboratory Feeding and the Wide Range of Resources.

By T. M. Rotch.

Diabetes in Infants and Young Children,

By H. B. WILCOX Rheumatic Affections in Children. A Clinical Study.

By F. L. Wachenheim.

Imperforate Anus, with the Report of a Case.

1. Modern Laboratory Feeding and the Wide Range of Resources .- Rotch notes the great advance which has been made in dealing with the nutrition of early life since 1891. All food stuffs can be classified as fats, carbohydrates, and proteids. and the proper selection of these is more important than following too rigidly the use of any patent or proprietary food. Physicians and laymen as a whole know too little about the principles of physiological chemistry, however much they may know about the use of the three classes of food stuffs. The author suggests a new prescription blank which would enable the physician to prepare a laboratory formula not only for the percentages of fat, lactose, and proteids but for various new foods including maltose, sucrose, dextrose, etc., thus doing away with the necessity for the use of patent foods. By means of this blank all combinations of the elements necescary for infants' food can be obtained at the laboratories, according to the indications in a given case. This card or blank explains in one column the function of the various substances which may be prescribed, the method of chemical action which they undergo in being used for a food mixture, maximum and minimum doses, and the time required to produce the necessary chemical changes. In another column are indicated the various substances which are to be used with their subdivisions, and the purpose which they are expected to accomplish, also general directions as to the use of the prepared formula. Another column is devoted to percentages which are written opposite each substance which the physician may wish to employ.

2. Diabetes in Infants and Young Children .-Wilcox thinks that in the treatment of this disease the physician's aim should be as follows: 1. To maintain the bodily nutrition at its highest level by general régime and feeding. 2. To keep the excre-tion of glucose in the urine at the lowest possible point. 3. To keep the urine free from acids. The following points are essential to the proper care of diabetics: 1. The determination of the type in each particular case, the ascertaining whether it is simply a carbohydrate incapacity or a deficiency in fat oxidation, as shown by acidosis. 2. The discovery of the particular carbohydrate which will be best tolerated by the patient. 3. A comprehensive method of recording data by which one can obtain exact information and make comparison between the

patient's weight; the amount of urine passed in twenty-four hours, with its specific gravity; the amount of sugar excreted; the quantity of acids present in the urine.

3. Rheumatic Affections in Children.-Wachenheim observes that these diseases are rare in infancy compared with their relative number at puberty. At the latter period they are among the common affections of childhood, coming next to the infectious diseases and the ordinary disorders of the gastrointestinal and respiratory tracts. They are more common in females than in males and are usually complicated with other diseases. In the acute cases given in the author's table the course was seldom severe, and salicylates were usually effective especially when supplemented by the In the subacute cases it is always necessary to exclude articular tuberculosis and gonor-rheal arthritis. The diagnosis in infancy and early childhood is very difficult; one must exclude scorbutic, septic, tuberculous, gonococcic, and pneumococcic joint disease. But after the third year muscular and joint pains must be closely scrutinized, and the heart examined. Sodium salicylate furnishes the best substance for drug treatment. Rest in bed, heat and immobilization are also very es-

Malignant Obstruction of the Œsophagus. -McGavin finds carcinoma the most frequent of all diseases of the œsophagus, occurring most frequently in males, and usually after fifty years of age. Nothing has been proved in regard to its embryonic causation; syphilis is probably an ætiological factor in some cases. Its most frequent location is at the bifurcation of the trachea. It tends to assume a ringlike formation and seldom progresses to the stomach. Metastases are of rare occurrence, and glandular involvement is usually late in occurrence. Dysphagia is practically its only early sign. The author considers the disease as it occurs within the lumen of the tube, within the wall of the tube, and as a result of pressure from the outside. The diagnosis may be made with the laryngoscope, with the finger, and by observations of the act of swallowing. but more precisely by radiography, by the passage of sounds, and by the esophagoscope. As to treatment the diseased structure may be extirpated but will usually recur, or esophagostomy without resection may be performed, or finally intubation and gastrostomy.

3. Cancer of the Breast. Indications for Operation.—English calls attention to the fact that there are many doubtful cases in which it is difficult to say whether an operation should be performed. The history of this portion of operative surgery is one of consistent progress, and many cases formerly considered hopeless are now treated with definite success. Even the cases in which the supraclavicular glands are involved may sometimes be submitted to operation. Such are those in which these glands though enlarged are not fixed. Should the glands be fixed behind the clavicle operation would be useless. In atrophic scirrhus the author advises early and thorough operation unless the patient is old and feeble, or there is some other obvious contraindication. Pregnancy should not be made a reason for postponement of surgical procedure. In bilateral carcinoma it will sometimes be better to operate first upon the breast which is more seriously diseased and after a fortnight or more to remove the other. Radical operation is excluded when (1) the growth is fixed to the thorax, (2) when the skin is extensively involved, (3) when the axillary vessels or nerves are implicated, (4) when there are deposits in the viscera or bones. In palliative operations the skin flaps should be so cut that the wound may heal by first intention.

5. The Treatment of Wry Neck by Lengthening the Sternomastoid.-Rowlands thinks the results of treating this condition by cutting the muscle subcutaneously or by the open method are by no means good, owing to the contraction of the newly formed fibrous tissue. The subcutaneous tenotomy is sufficient and safe in skilled hands and leaves no scar, but is not suitable for most cases, besides there is danger of wounding the internal jugular vein. It is safer to make a wound large enough to avoid the large vessels and nerves, and to make a thorough and safe division of the contracted structures. The fact that tendon lengthening is very successful in the treatment of talipes suggested to the author that lengthening the sternomastoid might also be effective. A curved incision is made across the lower end of this muscle which is then separated from the underlying vessels. The sternal tendon is then detached from the bone, and separated from the clavicular fibres, which are then divided obliquely upward and backward. The muscles are then stretched, the anterior fibres of the trapezius being also stretched. The two heads of the sternomastoid are then sewed together with catgut sutures, without tension, bleeding carefully arrested, and the wound dried and closed, the head being bandaged in the over corrected position. A supporting apparatus is worn for six months.

6. Some Recent Advances against the Tubercle Bacillus.- Eve finds recent work on this subject grouped under three headings: (1) The avenues of infection whereby the tubercle bacillus gains entrance to the body. (2) The intercommunicability of the human and bovine types of tubercle bacillus. (3) Treatment by the production of immunity with or without the aid of the opsonic index. The present tendency is to the view that the tubercle bacillus gains entrance generally by the bowel. As to the second point the evidence is abundant that tuberculous cows ought never to be used to supply milk for human food. As to the third point the chief hope

of fighting established tuberculous disease seems to be centered in the future of tuberculin. Other diagnostic methods are (a) an opsonic index outside the normal limits, (b) a transient fall followed by a more persistent elevation of the opsonic index in response to an injection of tuberculin or to autoinoculation produced by exercise, massage, or Bier's treatment, (c) the agglutination test of the patient's serum on an emulsion of tubercle bacilli, or (4) the method which is known as the deviation of the complement. Whatever method of treatment may be adopted in tubercular disease, success depends upon

7. Pyelitis during Pregnancy.—Hicks believes that pregnancy renders the urinary tract unusually vulnerable to bacterial invasion owing to hyperæmia, and urinary stasis resulting from pressure. It may intensify chronic renal disease, but under any circumstances the pelvis of the kidney frequently becomes infected during pregnancy, the bacilli gaining entrance directly from the colon. The condition is seldom an ascending one from the lower urinary tract. Pyelitis is usually on the right side only, but if secondary to cystitis both sides will be affected. In the ten cases which the author has seen, constipation was looked upon as the starting point in all of them, the renal pelvis being infected by way of the lymphatics. The condition usually begins with acute pain in the right renal region in the fifth to the seventh month of pregnancy, and temperature of 102° or 103° F. Pus will usually be found in the urine within forty-eight hours. The pyuria may persist for weeks, the pain and temperature will usually subside in two weeks. The general condition will depend upon the degree of toxic absorption. The prognosis is usually good, but there is a tendency to premature labor. The treatment is rest in bed, fluid diet, urinary antiseptics. Drainage of the pelvis is the main question to be considered.

- 2. Hernia.—Joseph Wiener remarks that a hernia need rarely be operated on during the first few or it becomes irreducible or strangulated. Taxis should be employed with the greatest care, not much force should be used, and it should not be perusually indicated in a reducible hernia which cannot be well retained by a truss, an irreducible hernia. a hernia which has once become incarcerated or strangulated, even though it be successfully reduced by taxis, and every strangulated hernia that cannot be reduced by taxis. The author believes that in the long run the greatest good to the greatest number will be accomplished by adhering to these con-

clusions, in support of which it must be borne in mind that we can at the present promise a complete cure to over ninety per cent. of nonstrangulated cases. Furthermore, the operative mortality in these cases will be practically nil; whereas, the operative mortality in strangulated cases is at least twenty-five per cent. Further marked improvement in the operative technique is hardly to be expected. The mortality can be lowered only by operating on more cases before the hernia becomes strangulated, and by operating at the earliest possible moment in the presence of strangulation.

5. Anæsthesia.—Neef says that the extensive use of ether and the experience that its incautious administration is fraught with but little immediate danger has gotten the hospital interne into reckless habits which cling to him in practice. There the anæsthetist finds himself frequently compelled to use chloroform, a narcotic many times more powerful than ether. In the hands of the inexperienced, and, above all, the inattentive, chloroform is certainly a dangerous drug. But this does not retract from its great value as an anæsthetic, and it would be illogical to condemn its use. In the aged we know that it is often not so much the operation itself as the bronchopneumonia that follows the anæsthesia which deserves grave consideration. Chloroform, or the chloroform ether combination, is undoubtedly, in such cases, preferable to pure ether, because it causes less bronchial irritation. In the morphine chloroform ether combination chloroform and ether are blended in a way most adequate for anæsthesia, and the system is so flexible that it readily adapts itself to an anomalous case. The difficulties in respiration so frequently encountered, even by the experienced anæsthetist, find a natural solution; if he has been studying the case he will be able to judge whether the trouble is due to crowding or to a mechanical cause. It should be remembered, whether the case is an apparently simple or critical one, that the good anæsthetist. just as the good surgeon, is he who, besides being competent, has a conscience and feels his responsibility; who appreciates that there are some who are anxiously awaiting the outcome and have a deep interest in the life that is in his hands.

SIXTH INTERNATIONAL CONGRESS ON TUBERCULOSIS.

Held in Washington, D. C., September 28, 29, and 30, and October 1, 2, and 3, 1908.

(Continued from page 717.)

Comman Min de a Silva Lysp II

The Ophthalmic Reaction.—Dr. Fernand Ar-Loing, of Lyons, said that from the clinical viewpoint the conjunctival reaction to tuberculin was sometimes accompanied by more or less marked dilatation of the rappl and much has frequently by meiosis. In his earlier experiences he had observed a kind of local anaphylaxis—a patient who had given a negative reaction on the first instilla-

tion would give a positive reaction on the second or third instillation. He had observed that after the hypodermic injection of tuberculin following the instillation into the eye, frequently the former test would be followed by a reproduction of the result of the latter. He considered, however, that this fact did not act as a contraindication to the employment of tuberculin hypodermically in the same subject. He found that a previous employment of tuberculin for therapeutic purposes had a very variable effect on the ocular test. He said that the ocular reaction was not free from danger. It was occasionally accompanied by prolonged conjunctivitis and by ulceration of the cornea. The previous instillation of a few drops of a I to 3,000 solution of adrenalin was capable of preventing excessively violent and prolonged reactions. As a result of his experimental researches he found that nontuberculous rabbits and horses that were poisoned with various microbic toxines gave positive reactions when tuberculin was instilled into the conjunctival sac. The rabbit, for instance, was more actively sensitized by typhoid toxine than by tuberculin, or at least to an equal degree. These facts showed that positive reactions might be obtained in nontuberculous subjects suffering from some other infection. Consequently, he considered the reaction to be an evidence of intoxication with any kind of toxine, and thought that the reaction was not absolutely specific in a theoretical sense, but had merely a relative value. The comparative study of the ocular reaction and the serum agglutination test showed that the two tests often gave positive results in the same individual; one of them might be present and the other absent, or they both might be present in varying intensity. He concluded that the ophthalmoreaction indicated that the organism was intoxicated with tuberculin; the serum reaction, on the other hand, showed a defensive reaction of the economy, while its intensity measured the degree of immunity of the individual to the tubercle bacillus. Therefore, it appeared to the author that at a certain point in the evolution of tuberculosis a positive ophthalmoreaction with a negative serum reaction indicated a doubtful prognosis, while the contrary would indicate a favorable outcome. When the two reactions were present in practically equal intensity, it showed that the organism was in a state of indifferent equilibrium and that the disease might end either in recovery or fatally. He considered the ophthalmoreaction to be a convenient and easily available diagnostic procedure; it sometimes failed in persons who were certainly tuberculous, and, on the other hand, it might be positive in subjects not suffering from tuberculous disease. Its diagnostic value, therefore, was not absolute, although it was quite accurate. The test was not always harmless, and it was not superior to the agglutination test. The latter procedure had the advantage of being absolutely harmless, more constant, and more delicate. Finally, the ophthalmoreaction was an indication rather of the degree of intoxication of the organism, while the agglutination reaction was an indication of the forces available for defense

The Application of the Differential Cutaneous Reaction in the Diagnosis, Pathology, and Treat-

ment of Tuberculosis.—Dr. Ladislaus Detre, of Budapest, said that his differential test for the variety of tuberculosis was a modification of the von Pirquet reaction. He applied concentrated old tuberculin, the filtrate of a culture of human tubercle bacilli, and the filtrate of a culture of bovine tubercle bacilli to the skin of the patient simultaneously. The reactions showed that the cases might be divided into four classes: (1) Those that were sensitive to the toxine, (2) those that were not sensitive to the toxine, (3) those that were positive to human tuberculin, and (4) those that were positive to bovine tuberculin. The author found that by his method ninety per cent. of the cases of pulmonary tuberculosis reacted to the human tuberculin, whereas in visceral and surgical cases, in adults, the reaction to bovine tuberculin could be demonstrated in from one third to one half the The decision as to which tuberculin was giving the reaction was made by observing which lesion was the more pronounced, because there would be a reaction to both tuberculins in the majority of the cases. He preferred, however, in the majority of the cases, to use the filtrate of the cultures rather than the tuberculins. He found that when a patient reacted more prominently to the human inoculation he never, upon subsequent inoculations, showed a predominance of the bovine reac-He thought that the determination of the reaction to human or bovine tubercle toxine should be determined whenever it was necessary to confirm a difficult diagnosis or to answer certain hygienic questions in regard to the carriers of in-The use of the test was valuable in the study of the question of the dualism or the unity of the Bacillus tuberculosis, and to answer the question of origin or of type of a certain bacillus, a tuberculin, or a filtrate. This question could be answered in from twenty-four to forty-eight hours by selecting the individual for the purpose of making the test according to his reaction to human or bovine tuberculin. The reaction type should be determined when for therapeutic purposes it was desirable to attempt to immunize a patient to the toxines of the bacilli. The author used the terms the "dominant" and the "concomitant toxine." It appeared that the dominant toxine was that derived from the type of bacillus with which the patient was infected, while the concomitant toxine was that derived from the opposite type of bacillus. He maintained that in immunizing work the patient would be tolerant of the concomitant toxine and could easily be immunized with it; but that he would be intolerant of the dominant toxine. Hence the therapeutist would select for his immunizing substance the toxine of the organisms corresponding to the tuberculin that gave the less marked reaction. He thought that by means of the systematic employment of the differential cutaneous reaction it was possible to immunize a patient against the toxine, provided, of course, that the clinical symptoms were kept under accurate observation, with much greater ease and certainty than had heretofore been possible. The technique was simpler, and the results were more objective, more certain, and more easily perceived than the results of the opsonin method.

COMBINED MEETING OF SECTIONS I AND VII.

THE RILATIONS OF HUMAN AND BOVING TUBERCULOSIS.

The Relations of Human and Bovine Tuberculosis .- Dr. Robert Koch, of Berlin, spoke of his statements concerning tuberculosis made at the London Congress in 1901. He said that Theobald Smith had been the first to divide the Bacillus tuberculosis into the two types, human and bovine. He said that after his statements in 1901 many experiments had been published to prove that human tubercle bacilli could infect cattle and that bovine bacilli could infect man. He referred to the difficulty of excluding infection in the natural way in any group of experiments. He particularly criticised the experiments made by the British Royal Commission. Some of the sources of error in interpreting experiments were the accidental contamination of cultures with organisms of the opposite type and the accidental occurrence of natural infection in the experimental animals. He said that a bacillus of the bovine type had never been found in a case of pulmonary tuberculosis, and that a distinctly human type of bacillus had never been found in a case of tuberculosis in cattle. He admitted that bacilli of the bovine type had been found in the lymph nodes of man in a few cases; but he said that these bacilli were not very virulent. Eleven twelfths of the victims of tuberculosis in the human family died of pulmonary tuberculosis and only one twelfth died from the other forms of the disease. Since no case of pulmonary tuberculosis had ever been recorded in which the bacillus was of the bovine type, he thought that the direct prophylactic problem was to destroy the human bacilli in the discharges from infected human beings. From a practical sanitary point of view, the infections with bovine bacilli could be disregarded, and all the energies of the sanitarian could be directed toward the extermination of the human type of the bacillus. He did not contend that the human and the bovine bacilli were distinct species of organism, but that they were not identical organisms; and he did not believe that one could be converted into the other.

The Relations of Human and Animal Tuberculosis, with Special Reference to the Question of the Transformation of Human and Other Types of the Tubercle Bacillus.—Dr. THEOBALD SMITH, of Boston, described certain experiments that he had undertaken to determine the possibility of transforming tubercle bacilli of the human type into tubercle bacilli of the bovine type. It was possible that in one or two cases bacilli of the bovine type had been isolated from sputum, but these cases were of extremely doubtful authenticity. Infection of human beings with the bovine bacillus was essentially an infection through the alimentary canal. In the experiments that he had instituted for the study of the question of the ability to infect bovines with human tubercle bacilli he had used (1) pure cultures only, (2) tuberculous tissues, and (3) tuberculous tissues and pure cultures alternately. In general, the results from the use of cultures alone proved negative. Experiments in which cultures and tissues alternately or tissues alone were used were in some instances positive. These positive results might have been due to the accidental introduction of new stains of bacilli or to the use of mixed cultures, to an augmentation of the virulence of the organisms, to the rehabilitation of old bovine cultures, or to the conversion of the human into the bovine bacillus. Probably most of the successful attempts meant that there was an increase in the virulence of the organism, and not a passage from one type of the bacillus into the other type. transformation of the bovine type of tubercle bacillus into the avian type of bacillus had been reported, but the conditions of the experiment made it possible that the bovine type culture had been contaminated with the avian type bacillus. It was impossible at present to accept the proposition that bacilli of the bovine type could be transformed into bacilli of the human type. It had been definitely proved that human tuberculosis could exist without bovine tuberculosis, and he instanced several countries in which no bovine tuberculosis was present, but in which human tuberculosis was common. He agreed that the important sanitary problem was to prevent the spread of human tuberculosis.

The Problems to be Solved in Dealing with Human and Bovine Tuberculosis.—Dr. G. SIMS WOODHEAD, of Cambridge, England, said that no one was an opponent of Dr. Koch, that the men working on the problems connected with tuberculosis were merely trying to solve some of the questions raised by that eminent scientist. He described the conditions of the experiments performed by the British Royal Commission, upon the outcome of which the Commission published their positive results in producing tuberculosis in calves by feeding with human tuberculous sputum. He had found a sufficiently large number of virulent tubercle bacilli in cases of alimentary infection in human beings to produce tuberculosis in cattle. He concluded that they had either found the human type of bacillus much raised in virulence, or that they had discovered bovine bacilli in human cases. One third of the cases of tuberculosis in children under five years of age were due to the bovine bacillus, and he maintained that attention must be paid to this factor in considering methods of prophylaxis. No campaign against the spread of tuberculosis could be undertaken in which this factor was not taken into consideration. He thought that the question of modification of the bacilli of the various types was of considerable importance. He considered infection to be a very slow process, and thought that it was quite within the range of possibility that, during the period that clapsed between the ingestion of the bacilli and the clinical manifestation of the disease, which might be several years, the bacilli might un-dergo transformation in their new environment.

Variations of the Tubercle Bacillus, Especially from the Standpoint of Virulence.—Dr. S. Artono, of Lyons, said that he was a staunch adherent of the theory of the unity of the tubercle bacillus. His studies concerning this point had involved experiments directed toward the explanation of the variations in the cultural characteristics, the morphological peculiarities, and the alterations in the virulence of the organisms. As early as in 1884 he had made experiments that showed that the human tubercle bacillus varied very much in virulence. His later were laid demonstrated that the

virulence of the human bacillus varied from that of the most active bovine bacilli to an almost complete loss of the power to produce tuberculosis in the animals into which it was inoculated. Other experiments developed a method of culture by which he was able to increase or lower the virulence of any culture at will. He was able by the use of these special methods to produce a tubercle bacillus that had its virulence so modified that it resembled the avian bacillus. From his own experiments and from the results of the experiments of others, he showed that the avian bacillus could be so modified in virulence that it would resemble the mammalian organism. From the results of these experiments the conclusion must be drawn that the variation in the virulence of the bacilli explained the differences in the gravity and the course of tuberculosis, and they showed the desirability of possessing prognostic methods of reliability, as well as sure diagnostic methods. He believed that the unity and fusion of the classic types of tuberculosis were demonstrated, and he emphasized the necessity of taking precautions against tuberculous virus of whatever origin.

Investigations into the Relations of Human and Bovine Tuberculosis and Tubercle Bacilli .-Dr. Johannes Fibiger and Dr. C. O. Yensen, of Copenhagen, said that their studies for the determination of virulence were made upon fifty-one cultures, forty-seven human and four bovine; for the variations in morphology upon twenty-eight cultures, fifteen human and thirteen bovine; for the cultural characteristics upon twenty-nine cultures; for the chemical relations of the bacilli upon thirtytwo cultures, and upon thirty-six cultures on media free from albumin. As a result of this study the authors could not admit a sharp separation between the two well known types of bacilli, although it was true that the majority of the cultures isolated from cattle possessed the qualities described as peculiar to the typus bovinus, and that the majority of the cultures isolated from human sputum corresponded to the typus humanus. There were some cultures, however, that must be considered as transition forms, having some of the characters of the bovine and others of the human type.

Recent Developments in Regard to the Relations of Human and Bovine Tuberclosis .-Dr. MAZYCK P. RAVENEL, of Madison, Wis., said that he hoped that the impression would not go out from the congress that any death from tuberculosis in any of its forms was of negligible value. He believed that the apparent difference between the bovine type of the tubercle bacillus and the human type of the bacillus was probably produced by the different environment in which the two organisms grew. He thought that the highly virulent type of bacillus usually seen in bovines had been filtered out from among numerous organisms of varying virulence by the natural resisting powers of the animal into which they had been inoculated. There was no doubt that the tissues of children who had died of tuberculosis contained bacilli of the bovine type. There was no good method of accurately determining the source of a given strain of bacilli obtained from the human body at autopsy. He believed, however, that it was possible to transform the boying type of bacillus into the human type of

the organism. He said that cows coughed up sputum and distributed it just as the members of the human family did, and that this sputum in the case of a tuberculous cow contained tubercle bacilli that were capable of spreading the disease. It had been proved that tubercle bacilli could pass through the wall of the intestine without leaving the least mark of their passage. They could also reach the lung through the thoracic duct within four hours after they had been introduced into the stomach, without leaving any trace of their passage. In other words, the tubercle bacillus, having entered the alimentary tract, reached the lungs by the same route that the food reached those organs. He believed that the bovine tubercle bacillus, having entered the human body, acted exactly like the human bacillus. A fair proportion of children and adults who were victims of tuberculosis had bovine tubercle bacilli in their tissues. He thought that every precaution should be taken against the contamination of milk and meat, and that the proportion of cases of tuberculosis due to the bovine bacillus was extremely important from the viewpoint of public health.

Wetters to the Editors.

STATE BOARD EXAMINATIONS.

ALBANY N. Y. Oct bee 8 1908.

To the Editors:

My attention has but recently been called to Dr. James A. Egan's letter in your issue of September 5th, commenting upon my paper on The Character of the State Board Examinations, which you had noticed editorially and approvingly on August 1st. While much disliking controversy and the discussion of minor matters like the phraseology of examination questions, I am nevertheless going to beg a little of your space to reply to this letter, because it illustrates better than anything that I could say the attitude of many members of our State examining boards, and it is this attitude which I am opposing, and shall continue to oppose, because it is indicative of a tendency which seems to me to be vicious and which must exercise a baneful influence upon the medical profession so long as it is allowed to govern the action of the boards. This attitude to which I refer may be summarized as follows: The assumption of universal knowledge in the medical branches which are the subject of examinations; the independence, impatience with interference, and arbitrary action which the mere holding of office so often engenders; and the unwillingness to receive advice or suggestions from teachers and others qualified to advise. As a matter of fact, the boards are not omniscient, and they should act justly and deliberately, and not despotically, and, above all. they should be willing to listen to the advice of teachers who, having no favors to ask, desire only to secure the correction of existing abuses and the improvement of our licensing system.

Dr. Egan's comments on my criticisms are important, because they are representative of the attitude of many of the boards. He either fails to see or refuses to admit that the essential fault with the paper which I criticised is that all five of the questions dealt with theoretical and general descriptive chemistry, and none of them with chemistry as related to medicine, unless very remotely. Some of them were proper enough in their place, as in a high school or college examination, but for the particular purpose intended I do not hesitate to say that the paper was as inappropriate and unsuitable as any that I ever saw. And in referring to the New York State examination paper in chemistry of October 2. 1907, he fails to see that, while a few such questions as those which constitute his entire paper are included with many others, the candidate has fifteen questions in all, from which he may select ten, and is entirely free to omit questions not related to medical subjects. The two papers are radically different, and, if Dr. Egan does not perceive this, the fact has no little significance and importance.

As to the use of the term "formula" for "equation," I beg to say that Dr. Egan is entirely in error in supposing that they are synonymous terms, if this is what he means by speaking of one as the "analogue" of the other, and he might have set himself right on this point by consulting any dictionary before making his comments. For an examiner in chemistry to confound one term with the other is as inexcusable as if an examiner in mathematics should use "chord" for "arc," or speak of a cylinder when a sphere was intended. Dr. Egan says: "Surely Dr. Tucker must be at a loss for words when he attempts to discredit the ability of a State examiner to formulate questions in a proper manner." I do not know just what this may mean, but certainly the examiner who prepared this particular paper stands discredited already, and in criticising it I have been at no loss for ideas, which would seem to be more important than words.

Again, whether the questions in the paper were taken from Remsen's College Chemistry or not is entirely immaterial, and Dr. Egan's defense of them on this ground indicates the entirely mistaken conception entertained by many examiners. Thousands of questions might be taken from standard works which would be quite inappropriate for a medical examination, and, while books of the class to which this particular chemistry belongs are well adapted to use in academies and colleges, they are seldom used in medical schools. Dr. Egan must know that in some of the leading medical colleges in this country no general chemistry at all is taught, and he is not correct when he says that this particular book is "used in the leading medical colleges of the United States," and if he had consulted the announcements of the schools, as I have done, he would not have made such a statement.

Dr. Egan's statement concerning the peculiar oxide of potassium which figures in question 5 is amusing, to say the least of it. Doubtless the K() that appeared in this question was a simple error. K2CO3 being intended, but even if we admit that such an oxide has an existence, I would ask whether Dr. Egan considers that a body not even mentioned in the last edition of Watts's Dictionary of Chemistry is a fair subject for an examination question in medicine! If he does think so, I fear he will find

few to agree with him.

And lastly, Dr. Egan fails to see that State examination papers in medicine should be adapted to others than "students," by which I suppose he means recent graduates. When I said that I doubted "whether one member in ten on our State boards, save perhaps the examiners in chemistry, could get forty per cent. on such a paper as this, I spoke advisedly. I did not say that recent graduates and men fresh from the study of general chemistry might not do so. Many men who appear before the State boards have been practising medicine for years, and the examination should be of such a nature as to test fairly their knowledge and determine their fitness to continue in practice, and if our State boards do not take this fact into consideration they need to be reformed, and the public will demand such reformation before long, and the creation of boards competent to deal intelligently and properly with the situation.

Dr. Egan's plaint that "it is difficult for examiners to prepare acceptable questions for six examinations yearly" is well calculated to excite our sympathy, but he can hardly expect it to be received as an excuse. WILLIS G. TUCKER.

Book Aotices.

[We publish full lists of books received, but we acknowledge no obligation to review them all. Nevertheless, so far as space permits, we review those in which we think our readers are likely to be interested.]

Fourth Annual Report of the Henry Phipps Institute for the Study, Treatment, and Prevention of Tuberculosis. February 1, 1906, to February 1, 1907. An Account of the General and Special Clinical and Pathological Work done by Members of the Staff at the Institute during the Year. Edited by JOSEPH WALSH, A. M., M. D. Phila-delphia: Henry Phipps Institute, 1908. Pp. 430.

Each succeeding annual report of the Henry Phipps Institute is found more interesting and valuable to the student of tuberculous disease. only is the material considered in the statistics constantly increased—there are now nearly five thousand cases on the records—but each report finds the records more complete. The reader is struck by the thoroughness with which the material is studied from pathological, clinical, and sociological aspects, and there comes to mind the vast amount of valuable clinical material which slips through our dispensaries and hospitals with no further attention than a superficial search for "teaching material" or at best a proper examination and a very incomplete record. A critical study of five thousand cases of even the much despised leg ulcer would no doubt demonstrate one or two truths that are new. Furthermore, every one of the five thousand patients would be considered as a person with a leg ulcer instead of a leg ulcer with a person. Thorough study and full records take time, and at the Phipps Institute the work is divided among a large and en-

It is somewhat difficult to form an opinion as to the clinical results obtained, as four years is too short a period, and the different stages of the disease are all considered together, but for city treatment and a mixed class of patients the results seem to be remarkably good.

The report of the medical director, Dr. Lawrence Flick, is a general review of the statistical data, clinical and sociological, of the year. It deals with a remarkable number of items, and Dr. Flick's deductions from the statistics are conservative and reasonable. Some of the figures might be a little more explicitly defined, such, for instance, as the tables relating to temperature, pulse, and respiration. Here it is not stated whether the figures refer to the record on admission or to the maximum temperature, etc. Dr. Flick unconsciously corrects his own statement that a temperature of 100°, a pulse of 100, and a respiratory rate of 30 represent about the same relative disturbance, by statistics showing that "the percentage of cases which had a disturbance above this is much the highest in the pulse rate; next highest in the temperature; and lowest in the respiratory rate." Among the points brought out in this paper is the demonstration that there is no relation between the prevalence of right sided pulmonary tuberculous disease and right handed-

Dr. George B. Wood's study on the importance of the upper respiratory tract in the ætiology of cryptogenic infections, especially in relation to pleurisy, is of peculiar interest. According to Wood, the anatomical arrangement of the cervical lymphatics, with rare exceptions, precludes the possibility of a direct extension of infection from the tonsil to

The Pathological Report of the Year, by Dr. C. Y. White, is a record of sixty-six exhaustive autopsies, and furnishes an interesting study of the pathology of advanced tuberculous disease. The report of the bacteriologist, Dr. J. W. Irwin, brings out strikingly the rôle of the pyogenic bacteria as a terminal factor in the disease

A Comparison of the Pathological Findings with the Recorded Clinical Signs in Nine Cases of Tuberculosis of the Lungs, by Dr. Joseph Walsh, is a study in physical diagnosis checked by autopsy findings. The importance of such a study is self evident, and we are glad to note that Dr. Walsh intends to enlarge his series.

Other papers on the urine, the blood, the laryngeal findings, the pleura, the bones and joints, the relation of the pneumococcus to hæmorrhage, etc., represent a large amount of work and are well worth

Manual of Psychiatry. By J. Rogues de Fursac, M. D., Formerly Chief of Clinic at the Medical Faculty of Paris, Physician in Chief of the Public Insane Asylums of the Seine Department. Authorized Translation from the French by A. J. Rosanoff, M. D., Second Assistant Physician, Kings Park State Hospital, N. Y. Second American from the Second French Edition. Revited and Enlarged. New York: John Wiley & Sons: London: Chapman & Hall, Limited, 1908. Pp. 1x-406.

Attention has been called to the first edition of Fursac's manual. This author is one of the most thoroughgoing of the younger French school to accept the teachings of Kraepelin, and as such has given in short compass an excellent, though superficial, résumé of this author's teachings. It may be read with profit by those particularly who are unable to correlate French and German teachings in this difficult branch of medicine.

The translation has been well done, and many

crudities and even inaccuracies of the first edition have been eliminated. The French délire, we note, is correctly handled in this edition, whereas in the first there was much confusion in the translation of the term.

Public Health and Marine Hospital Service:

Official list of changes of stations and duties of commissioned and other officers of the United States Public Health and Marine Hospital Service for the seven days ending October 7. 1408:

BLANCHARD, J. F., Acting Assistant Surgeon. Granted two days' leave of absence from October 7, 1908, under par-

days' leave of absence from October 7, 1908, under paragraph 210, Service Regulations.

BRYAN, W. M., Assistant Surgeon. Granted thirty days' leave of absence, from November 1, 1908.

CARRINGTON, P. M., Surgeon. Directed to report at the Bureau upon special temporary duty October 3, 1908.

CARRINGTON, P. M., Surgeon. Relieved from special temporary duty at Washington, D. C., October 6, 1908.

Detailed to represent the Service at the Association of Williamy Surgeons at Atlanta Ga. October 12, 15, 16. Military Surgeons at Atlanta, Ga., October 13 to 16,

CARRINGTON, P. M., Surgeon. Granted six days' leave of absence while en roule to join station.

EARL, F. D., Acting Assistant Surgeon. Granted seven days' leave of absence, from October 7, 1908, and excused without pay for two days from October 14, 1908.

GOLDSEOROUGH, B. W., Acting Assistant Surgeon. Leave of absence for five days, granted September 16, 1908, amended to read three days.

amended to read three days.

Lewis, F. S., Acting Assistant Surgeon. Granted six

weeks' leave of absence, from September 20, 1908.

Marsillan, C. J., Acting Assistant Surgeon. Granted thirty days' extension of annual leave, from July 21, 1908, on account of sickness, and twenty-five days

thirty days' extension of annual leave, from July 21, 1908, on account of sickness, and twenty-five days' leave, from August 20, 1908.

RIDLON, J. R., Acting Assistant Surgeon. Directed to proceed to Stapleton, N. Y., for duty, reporting to Commanding officer, Marine Hospital.

WALKER, R. T., Acting Assistant Surgeon. Granted four days' leave of absence, from October 26, 1908, under paragraph 210, Service Regulations.

WERTENBAKER, C. P., Surgeon. Granted seven days' leave of absence, from October 5, 1908.

WERTENBAKER, C. P., Surgeon. Detailed to represent the Service at the Association of Military Surgeons at Atlanta, Ga., October 13 to 16, 1908.

WETMORE, W. O., Acting Assistant Surgeon. Granted three days' leave of absence, from September 10, 1908, under pararaph 210, Service Regulations.

WHITE, J. H., Surgeon. Detailed to represent the Service at the meeting of the Southern Medical Association at Atlanta, Ga., November 10 to 12, 1908.

WHITE, M. J., Passed Assistant Surgeon. Detailed to represent the Service at the Association of Military Surgeons at Atlanta, Ga., November 10 to 12, 1908.

Dr. J. R. Ridlon appointed an acting assistant surgeon for duty at Stapleton, N. Y., September 30, 1908.

Board of medical officers convened to meet at the Marine Hospital, Chicago, Ill., October 7, 1908, for the purpose of making a physical examination of an applicant for the position of cadet in the Revenue Cutter Service: Surgeon G. B. Young, chairman; Assistant Surgeon C. E.

Board of medical officers convened to meet at the Marine Hospital, Savannah, Ga., October 7, 1908, for the purpose of making a physical examination of an applicant for the position of cadet in the Revenue Cutter Service: Surgeon F. W. Mead, chairman; Acting Assistant Surgeon A.

Army Intelligence:

Official list of changes in the stations and duties of officers of the medical corps of the United States Army for the week ending October 10, 1908.

Barney, Fred M., First Licutenant, Medical Reserve Corps. Ordered from Fort Myer, Va., to Fort McHenry, Md., for temporary duty.

BAYLEY, EDMUND W., First Lieutenant, Medical Reserve Corps. Granted leave of absence for one month. BOWMAN, MADISON M., First Lieutenant, Medical Reserve

Corps, and Patterson, Edwin W., First Lieutenant, Medical Reserve Corps, relieved from duty in the Philippines Division, and ordered to the United States for

DUTCHER, BASIL H., Major, Medical Corps. Ordered to duty at Plattsburg Barracks, N. Y., at the expiration of his present leave of absence.

FOLEY, THOMAS M., First Lieutenant, Medical Reserve Corps. Assigned to active duty, and ordered to Fort

Moultrie, S. C., for duty.

FORD, CLYDE S., Captain, Medical Corps. Relieved from duty in the Philippines Division, June 15, 1909, and ordered to the United States; granted six months. leave of absence about December 15, 1908, with permission to go beyond the sea

Stoff to go beyond the sea.

FREEMAN, PAUL L., Captain, Medical Corps. Granted leave of absence for ten days.

HARRIS, JESSE R., Captain, Medical Corps. Granted an extension of twelve days to his leave of absence.

HAVARD, VALERY, Colonel, Medical Corps, and LYNCH, CHARLES, Major, Medical Corps. Detailed to represent the medical dearthcast of the Army at the prefixed of the medical department of the Army at the meeting of the Association of Military Surgeons, at Atlanta, Ga.,

October 13 to 16, 1908.

Hoff, John van R., Colonel, Medical Corps. Relieved from duty in the Philippines Division. December 3, 1908, and ordered to proceed to San Francisco, Cal., for fur-

KEAN, JEFFERSON R., Major, Medical Corps. Detailed to represent the medical department of the Army at the meeting of the Association of Military Surgeons, Atlanta, Ga., October 13 to 16, 1908, and on completion of that duty to rejoin his station in Cuba, having completed the duty for which he was ordered to the United

MABEE, JAMES I., Captain, Medical Corps. Granted an ex-

tension of two months to his leave of absence.

Schier, Anton R., First Lieutenant, Medical Reserve Corps. Honorably discharged from the service of the United States.

SNYDER, CRAIG R., Captain, Medical Corps. Granted leave of absence for one month.

SLAYTER, JOHN T. H., First Lieutenant, Medical Reserve Corps. Ordered to proceed from Fort William Henry Lawring Mark to his home Cambridge Mark and Harrison, Mont., to his home, Cambridge, Mass., and

STEPHENSON, WILLIAM, Major, Medical Corps, and PHIL-LIPS, JOHN L., Major, Medical Corps, Having com pleted examination for promotion at Washington, D. C., ordered to return to their proper stations.

Navy Intelligence:

Official list of changes in the stations and duties of officers of the medical corps of the United States Navy for

the week ending October 10, 1908:

Cottle, G. F., Assistant Surgeon. Appointed an assistant surgeon, from October 3, 1908; ordered to a course of instruction at the Nava! Medical School, Washington,

DE FIGANIERE, P. A., Acting Assistant Surgeon. Appointed dered to a course of instruction at the Naval Medical

School, Washington, D. C.

Donce, A. H., Assistant Surgeon. Appointed an assistant surgeon, from October 3, 1908; ordered to a course of instruction at the Naval Medical School, Washington,

FARWELL, W. G., Passed Assistant Surgeon. from the Marine Recruiting Station, Philadelphia, Pa, and ordered to duty at the Naval Hospital, Philadelphia Pa.

FREEMAN, G. F., Surgeon. Commissioned a surgeon, from

August 2, 1908.
Higgins, M. E., Assistant Surgeon. Detached from the *Illinois* and ordered to the Naval Hospital, Canacao,

KOLTES, F. TES, F. X., Assistant Surgeon. Detached from the Connecticut and ordered to the Wilmington.

Mann, W. L., Assistant Surgeon. Appointed an assistant surgeon, from October 3, 1908; ordered to a course of instruction at the Naval Medical School, Washington,

MURPHY, J. A., Surgeon. Ordered to the Franklin.

POLLARD, J. B., Assistant Surgeon. Appointed an assistant surgeon, from October 3, 1908; ordered to a course of instruction at the Naval Medical School, Washington,

SMITH, H. L., Assistant Surgeon. Detached from the Missouri and ordered to the Villalobos.
SNYDER, J. J., Surgeon. Unexpired portion of leave re-voked; detached from the Franklin and ordered to the Marine Recruiting Station, Philadelphia, Pa.

Births, Marriages, and Beaths.

BALCOM—VON DÜRSCH.—In Providence, Rhode Island, on Monday, October 5th, Dr. F. O. Balcom and Miss Marie Eugenia von Dürsch.

DRAPER—FIRADEN.—In Shelbyville, New York, on Wednesday, October 14th, Dr. Edwin Lyon Draper and Miss Mary Frances Headen. EVANS—MORROW.—In Philadelphia, on Wednesday, Sep-

tember 30th, Dr. Roland Curtin Evans and Miss Jane

FISHER-BULLOUGH .- In Washington, D. C., on Wednesday, October 7th, Dr. Raymond Adams Fisher and Miss Elizabeth Stafford Bullough.

Greene-McKnew.—In Washington, D. C., on Wednesday. October 14th, Dr. Samuel H. Greene, Jr., and Miss Edna Isabelle McKnew.

ANDERSON.-In Salem, Ohio, on Thursday, October 1st, James Anderson, aged fifty-seven years

BIRCHMORE.—In Philadelphia, on Friday, October 2d, Dr. Woodbridge Hall Birchmore.

BLAIR.—In Cincinnati, Ohio, on Monday, October 5th, Dr.

J. J. Blair, aged sixty-one years.

Greenough.—In Boston, on Friday, October 2d, Dr. Eustace W. Greenough, of New Bedford, Massachusetts. aged twenty-nine years.

HADLOCK.—In Oswego, New York, on Thursday, October 8th, Dr. J. W. Hadlock, aged seventy-one years.

Heidemann.—In Elmhurst, Illinois, on Tuesday, Septem-

ber 20th, Dr. George F. Heidemann, aged seventy years.
Herschler.—In Buffalo, New York, on Thursday, October 1st, Dr. Albert A. Herschler, aged twenty-four years.
Holsten.—In Bridgeport, Montgomery County, Pennsylvania, on Friday, October 2d, Dr. George W. Holstein. aged eighty-seven years.

aged eighty-seven years.

KATTENHORN.—In Cincinnati, Ohio, on Saturday, October
3d, Dr. Henry F. Kattenhorn, aged thirty-nine years.

Loch.—In Norristown, Pennsylvania, on Saturday, September 26th, Dr. John W. Loch, aged seventy-eight years.

McGAUGHEY.—In Winona, Minnesota, on Sunday, September 27th, Dr. J. W. McGaughey, aged seventy years.

PARTZ.—In Philadelphia, on Sunday, October 4th, Dr.

August Partz.

Rogers.-In Harrisonburg, Rockingham County, Virginia, on Saturday, October 3d, Dr. H. M. Rogers, aged forty-

SALE.-In Bedford City, Virginia, on Saturday, October 3d, Dr. Frederick Sale, son of Dr. John W. Sale

SANDERS.—In Booneville, Kentucky, on Saturday, October 3d, Dr. S. G. Sanders.

Stern.—In New York, on Thursday, October 1st. Dr.

WISWELL.—In Philadelphia, on Sunday, September 27th, Dr. Miranda P. Wiswell.

Woon.—In Chicago, on Saturday, September 26th, Dr. Samuel E. Wood, aged sixty-nine years.

THE ALCOHOLIC PSYCHOSES. CHRONIC ALCO-HOLIC DELIRIUM (KORSAKOFF'S PSYCHOSIS).

A Chineal Lecture.

By Smith Ely Jelliffe, M. D., Ph. D., New York,

Clinical Professor of Psychiatry, Fordham University; Visiting Neurologist, City Hospital; Attending Physician, New York Hospital for Nervous Diseases.

I have already pointed out the immense rôle that the various types of intoxications play in the development of mental disturbances. We have seen that the toxic, infectious, and exhaustion psychoses have many signs in common, and that it may, for instance, be impossible to distinguish the mental disturbance due to the toxine of the influenza bacillus, from that due to the typhoid organism, i. e., seen purely from the mental side.

This same truth is to be seen in a much less marked form in the consideration of the toxemias of a genesis, chemically speaking, much more definite. For in the specialized type of mental disturbance, Korsakoff's psychosis—or polyneuritic psychosis—of which we shall speak, it is well known that the symptomatology will show a fairly uniform picture, notwithstanding a very marked variation in ætiology—alcohols, certain metals, lead, arsenic, diabetes, tuberculosis, carcinoma, puerperal infection at a series of the ser

tion, etc. We have just opened the discussion on alcohol in its relations to mental disturbance, and I have given you a picture of the effect of alcohol in its power to dissociate the mechanisms of both mental and neural integration: We have gone hastily over the subject of acute drunkenness, which from a medical point of view is a very definite psychosis. Whether it should be regarded as an insanity from the standpoint of legal requirements is a knotty problem. We have discussed that type of subacute or chronic poisoning known as delirium tremens; noted the extreme variability in its various aspects, and I have tried to show that in the analysis of this type of alcoholic delirium we may find many practical suggestions as to how to study other mental The relation of acute hallucinosis disturbances. to delirium tremens and to other forms of mental disturbance has been pointed out. You have been warned not to confound this type of an alcoholic psychosis with other more sinister mental disturbThere remains for discussion but two other fairly well crystallized groups in this alcoholic medley—those forms which show a tendency to chronic delusional development—the so called alcoholic paranoias, and the mental disturbance which is associated with a more or less marked degree of polyneuritis, the so called polyneuritic psychosis, or Korsakoff's psychosis. We shall take up the latter this afternoon.

History.—Alcohol has been the boon companion of man ever since we have any records. Acute and chronic drunkenness have probably always existed, and it is inconceivable that multiple neuritis with marked mental symptoms did not occur in ancient Greece and Rome; yet we cannot credit the Greeks this time with the knowledge of a polyneuritic psychosis. Magnus Huss has recorded that mental symptoms accompany neuritis as early as 1849.

The term Korsakoff's psychosis is more or less popular at the present time: Jolly, professor at Beriin, having used the term first in 1897. Up to the present time no one has shown that Korsakoff's description is not the first fairly complete and accurate account that we have. It is true that Jackson, in America, as early as 1822, in describing alcoholic multiple neuritis, says that in these cases "the mind is weakened, but that it is free from delirium ordinarily," from which by inference we learn that Jackson recognized the occasional presence of delirium.

Dr. M. Allen Starr, in his Middleton Goldsmith lectures in 1887, on Multiple Neuritis and its Relation to Certain Peripheral Neuroses, *Medical News*, February 5, 1887, p. 141, makes the following remarks concerning the mental features in certain cases of multiple neuritis:

One feature of alcoholic paralysis remains to be noted, viz., the cerebral symptoms. These are hardly ever wanting. There is, first, the excitement rising to the degree of active delirium, with illusions and hallucinations of the various senses: there is the insomnia which so soon exhausts the patient if it is not remedied; there is the loss of memory, especially of recent occurrences; and the lack of power of attention or concentration which prevents intelligent conversation. The indifference to bodily wants may be so great as to lead to uncleanliness, and since paralysis of the sphincter is the rare exception, incontinence is usually to be ascribed to the mental state. It is impossible to get any reliable history of their illness from these partients. Their statements are unintelligible or unreliable; and here it may be well to notice a symptom first described by Strümpell. These patients will relate occurrences as having happened recently with such elaboration of detail, when, as a matter of fact, the story is entirely a product of the imagination. Thus, one patient of my own, who had been confined to bed for many days, told me one afternoon that she had been out to see an eminent gynæcol-

¹Compare Dupré. Traite de pathologie mentale, 1p. 1131-1140, where a full list of atiological factors, some twenty-six or twenty-seven, are listed.

ogist during the morning, had gone to his office and waited for him several hours; had seen other patients there, and finally had been told by the doctor's brother that he would not return in time to see her, so she had come home again. And this was all related in apparent good faith, so that I have no doubt that she believed that what she said had occurred. With the possibilities of such delusions in view, it is evident that the statements of these patients cannot be accepted regarding anything, especially as to their own history. One patient who was admitted to Bellevue, during my service there, told me a different story of her case every day for a week, and it was only by interviewing her friends that the correct account was obtained.

In Starr's account it cannot be said that he grasped the causes for the falsifications of memory. He calls these statements delusions.

Names, after all, are but symbols standing for things, and the only requirement that science demands is that when a symbol is used, the user should have a clear and thorough idea of what is meant. It is for this reason that I shall quote to you at some length fragments from descriptions given by Korsakoff himself—then a privatdocent in the University of Moscow. I cannot give you his earliest descriptions, as they are published in Russian,3 but in 1890 (Archiv für Psychiatrie, xxii, p. 669), under the title of Ueber eine besondere Form psychischer Störung combinirt mit multipler Neuritis, he first calls attention to his earlier paper, published in (Vestnik Dushevnikl Polieznei, iv. No. 2) 1887, in which he describes a peculiar form of mental disturbance occurring in cases of multiple neuritis of nonalcoholic origin. This psychic disturbance is sometimes characterized by a very definite irritable weakness in the psychic sphere, at times in the form of confusion with marked characteristic mistakes with reference to place, time, and situation, and at times as a nearly pure form of acute amnesia in which memories of very recent events are profoundly modified, while events which took place in the past remain comparatively intact. Such a form of psychic disturbance, he writes, is highly characteristic of multiple neuritis of alcoholic origin. It does not, however, belong to alcoholic neuritis exclusively, but occurs in forms of neuritis due to other toxic agents, chief of which he held were toxæmias of gastrointestinal origin.

Korsakoff was aware of the fact that in literature there had been cases of multiple neuritis reported, in which psychic symptoms had been noted, but such mental abnormalities had not been carefully analyzed. In the article which I show you he reports two of his earlier cases showing the characteristic mental symptoms, in whom the neuritis was not of alcoholic origin. He then proposes the name cerebropathia psychica toxæmica-then follows the description of six cases of alcoholic multiple neuritis with the characteristic symptom picture.

These are the six cases which I have had the opportunity to observe in the past two years. They all have much in common; in the first place the psychic alterations bear a close resemblance. It is true that these vary, in one case being more marked, in another milder—but in all the most prominent symptom was a more or less deep disturbance of association of ideas and of the memories. In the severer cases there developed a complete loss of relation between the single ideas, while in the milder cases the ideas simply were mixed, the memories were tossed about, and

forgetfulness was very striking. In all of these cases it was specially characteristic that there was a marked confusion with reference to different occurrences, which often had no foundation in fact, which the patient would narrate in the most natural manner. In one case there was added to this condition a state of emotionalism, of anxiety, with accompanying hallucinations and illusions.

The presence of a neuritis was a second characteristic present in all cases, although varying considerably in its intensity. All cases showed weakness in gait, the rectus

femoris being involved.

Speech disturbances were noted by him, and in one case nystagmus. Summing up (p. 700) Korsakoff gives the following very terse description, which naturally has been somewhat enlarged at the

The fundamental symptoms of the disease are, as a rule, the following: A high grade of irritable weakness of the psychic spheres, then a more or less deep disturbance of association of ideas, and finally a clouding of memories. The weakest expression of the involvement of the psychic spheres in this disease seems to be an irritable weakness which shows itself in sleeplessness, in easy tire of the brain, which gives rise to fear and anxiety. Toward evening especially, the patients are easily excited, fear something, wait for something, literally are discontented with everything. To this, not uncommonly, may be added inability to concentrate the attention and the impossibility of ridding themselves of certain ideas, by reason of which compulsory ideas arise which are often of exciting or fearful nature.

Associated with these ideas arise many strange and impossible wishes. If the psychic disturbances go deeper the impossibility of the correct effort of thought becomes apparent, the attention is not any longer in a position to lead to the association of ideas, these ideas therefore become mixed, inconsequent, and incorrect in consciousness. Such a condition may develop acutely even in the beginning of the disease, or simultaneously with the initial symptoms of the multiple neuritis, occasionally before. In the majority of cases there arises in the beginning a condition of strong emotional disturbance, chiefly in the form of fear (panophobia) accompanied by distinct delirium, hallucinations, and emotional conduct. This irritable condition, as a rule, does not last very long, but either passes over into recovery or into a chronic state. This chronic form bears the character of a stuporous dementia, or an apathetic confusion.

The stuporous dementia shows itself in a deep disturbance of judgment, with associated delirious ideas, illusions, and hallucinations, often with short attacks of fury. In some cases the dementia reaches a very high grade, the patients become weak minded, uncleanly. During this period the symptoms of multiple neuritis such as an irregular, weak gait, disturbances of the patellar reflex, tremor of the extremities, sometimes due to the involvement of the cranial nerves, may all be present, so that one may confound the disease with paresis, and be surprised to find the patient get well. For the most part, however, such cases of neuritic pseudoparalysis are comparatively few

Cases with simple stupor, or with temporary excitement where the patients either get well in from five to nine months, or remain unchanged are the more common.

In other cases the chronic form of this disorder shows the character of an apathetic confusion, occasionally as an end stage there arises an acute hallucinatory fury with confusion, in other cases it develops gradually without any going on to such a furious stage. It is characterized by confusion of ideas, disorientation with reference to time and place, numerous mistakes and weaknesses in memory. The patients often do not know where they are, even when they are in their own rooms, confound the persons about them, call them by the names of those long dead, accredit to themselves actions which they have never done. These patients mix in a remarkable manner ideas of real facts with old memories to form very peculiar combinations of thought; the memory is as a rule deeply disturbed, the patients often forgetting everything of what goes on around them. As a rule such patients are comparatively quiet, apathetic, emotional states do not arise, at times there is a mild tendency to laugh or cry, and many patients who are quiet in the day time are excitable at night, talk constantly, cry aloud, are quarrelsome, want to get up and go about.

This form of confusion is most common, it appears in

S. L. (1) In Presidence, here f is then Later been the effect meanth of the fire the values of a stream, art term for the new later f is f or f is the effect of the f or f or f is f or f

more marked, or less marked degrees, sometimes passing away with comparative rapidity, again persisting for a long time. For the most part it increases gradually and becomes so marked that the patient not only confounds acquaintances with strangers, but loses entirely the significance of

objects, words, and signs.

I have already said that in this form there is nearly always a clouding of memory, of a greater or lesser in-tensity, but there do occur forms of psychoses in neuritis in which the memory is disturbed, but there is a relative clarity of consciousness and of judgment. In these cases it is highly striking how the same patient, who is able to grasp clearly everything about him, who is able to follow serious conversation, yet whose memory is so distinctly involved that he literally forgets everything that has been said, and this forgetfulness reaches such a grade that the patient, five minutes after his lunch, does not remember that he has eaten it, he forgets with whom he has been, and what he has said. Amnesiæ of this type (amnesia acuta) limit themselves mostly in that occurrences which have taken place since the beginning of the disease, or shortly before, are forgotten, whereas that which has occurred in times long past often remains clear in the memory. The more severe the case, as a rule, the deeper is the amnesia In severe cases the memory of old events may also be bad, and in the mild cases recent events may not be entirely forgotten, but there is above all a forgetfulness, an inaccurate memory of time, etc., apparent.

The symptoms of the multiple neuritis, and the appear-

ance in the peripheral nervous system are not always developed in the same way in this disorder. In some cases they preponderate so that the psychic alterations, consisting for the most part only in an irritable weakness, constitute the background. Thus in some there arises a very severe form of multiple neuritis, which runs the course of an acute ascending paralysis, in others there is a long drawn out severe form of paralysis, hyperalgesia contributes and muscle atrophies. In other forms the peripheral and psychic symptoms show with equal force, and finally there are other forms in which the physical symptoms of neuritis may be present in mild degree, and may be entirely overlooked. This stage may be limited solely to the occur rence of paræsthesiæ in the extremities (feeling of coldness, feeling of binding about the feet or hands, tickling as of crawling of ants) with mild disturbances of coordination, and ready fatiguability in walking associated with altera-tions of the patellar reflexes, and mild pains in the extremities. Such cases should awaken our special interest since they come mostly to the attention of the practitioner.

In addition to the appearance of multiple neuritis, other symptoms appear which indicate disturbances of the nervous system; often they point to a local disease of the brain. Again the symptoms are those of a spinal cord disorder, then they seem to point to an independent disease of the muscles, a myositis which may be spread over many muscles. Nearly always there are signs which prompt one to state that the entire body is involved. General loss of flesh is noticed with a very distinct loss of power; the pulse is often very rapid and irregular and the urine is usually deep colored, in quantity, and shows a relatively high percentage of destructive products. Disturbances in the intestinal canal, obstinate vomiting, retained menses, and a slight increase

of temperature, etc., are usually found.

The course of the disease is also interesting and characteristic. For the most part it arises in consequence of a definite cause, whether that be exposure to cold, a previous acute disease, poisoning, or marked fatigue, or by a cachexia, which arises at the same time. Very frequently the disease begins with obstinate vomiting, following which the appearance of psychical disturbance in one or another form takes place. Frequently at the same time, often earlier, not seldom later the appearances on the part of the peripheral nervous system show themselves.

According to the onset whereby the disease is developed it may run an acute course, and reach its maximum in a short time. For the most part, however, it runs a subacute short time. course, and less seldom a very slow chronic course occurs.

If the disease develops on the basis of an incurable cachexia it terminates with the death of the patient, if this is not the case, however, there follows after the acute period of the disease, a second period in which the condition improves, the psychic and physical symptoms recovering in parallel manner. There are certain cases in which the psychic symptoms clear up sooner than the physical ones, and vice versa, where symptoms of the psychic alteration still remain after the disappearance of the multiple

The improvement is usually accompanied by a general increase in the strength, the interrupted functions again take their place, the body weight commences to improve, especially the functions of the nerves increase.

Very frequently there remains, after the cure, a very marked fatiguability of the nervous system, especially in the psychic sphere, and a great tendency to a recurrence.

With this description in mind as an original from the founder of this disorder, let me turn your attention to a patient who was admitted to the City Hospital about ten days ago.

CASE I.--J. K., twenty-nine years of age, a traveling salesman, an active, intelligent, able man.

This patient, as you see him lying in bed, presents an interesting type of physiognomy, to which I would like to call your close attention. It is neither normal nor yet markedly abnormal. You see that it expresses a fair de-gree of alertness but is a trifle stupid save when he smiles, which, as you notice, he does not infrequently. This slightly stupid expression, when you come to analyze it, is dependent largely upon the fact that the skin is swollen, the lips are slightly swollen, the eyelids droop somewhat, the eye-balls are slightly injected, and the fine veins of the nose and cheeks are somewhat prominent. The color of the face is a trifle unhealthy, being a little less bright as far as the lips and conjunctivæ are concerned than they should be, as though there were some modification of the aeration of the blood, which is probably accounted for by the somewhat quick and altered breathing.

In response to a question as to his name he tells you. with a laugh, that it is somewhat silly, that it is J. K.; that he is twenty-nine years of age, that he has been a traveling salesman selling shoes, and on asking him where he is, you will notice that he looks around, and says that he guesses he is here, and on wanting to know where "here" is, he tells us that "it looks like a hospital," and in response to the question "How long have you been here?" he tells us that he arrived this morning (whereas as a matter of fact he has been here nearly ten days). You may have noted that as I gave him my hand to shake, as we approached the bed, he lay motionless and nodded, but beyond some ineffectual movements of the arms was unable to take my hand. We shall examine into this a little later. On asking him what is the matter with him, he tells us that he feels all right; "Why do you not get up and walk?" you will note that his response is that he was up all the morning. out on the roof, and that the day before he had been walking all day, and he did not feel like getting up just now.

As he talks, note that his speech is somewhat halting, that the muscles of his face show slight tremors, and that his tongue, as he shows it to us, is coated and tremulous. He was partially asleep, you will recall, as we approached the bed, and should you turn away, you will find that he

will become somnolent again, or even seem stuporous. Testing his sense of smell, his sight, his hearing, his taste, his feeling to pin prick, etc., you will note that he answers more or less correctly. You will note that when I first approached him, some four or five minutes ago, I in-I hist approached him, some root of the himstes ago, I his troduced myself, and introduced you all as members of a class of young physicians interested in the study of mental disorders, and I now ask him what is my name, and you will notice that he is unable to reproduce it, and I tell it to him again at this time, and will ask you to remind me to ask him the same question again when we have finished our investigations. I will also tell him at this time the "polar story from your Outlines of Psychiatry with which you are familiar, and will ask him to try and tell it to us again at the close of the clinic, impressing on him the necessity for his holding it in his memory.

ty for his holding it in his hields?.

Further you will notice that as I ask him again where he had talls us that he is in the store. "What store?" is he tells us that he is in the store. "What store?" "Macy's"; and should we test him still further you would find that there is a very distinct loss of orientation, which as we have seen already involves time, since he has not been out of bed for ten days, and yet he tells us that he only arrived to-day; and so far as orientation in place is concerned his answers are still more confused and con-

tradictory.

Let us see what he did yesterday when he said he was

out walking all day. In response to my suggestion, "You remember that we sat on the wall and were fishing," he says "O yes! and those were pretty good fish that we caught." And in response to my further suggestion that it was a fine haul, he says, "Yes, more than three men could carry home," and I then am able to lead him to the story of a horseback ride that he took this morning with me, and with one of you whom I point out and whom he remembers perfectly as having been with him.

I call particular attention to this type of suggestion confabulation in this disorder which we have before us. It is very typical. As he still further rambles on, you will notice that he gives a very highly colored picture of his ac-tivities for the past week, he tells us of deeds that he has performed, which, in spite of the fact that he has been helpless in bed, paralyzed in his hands and feet, do not

seem to him to be at all incongruous.

You will notice that throughout all this conversation, my questions and his answers, that he is fairly alert, that his attention is fairly easily gained, but that he very rapidly wanders off into other fields which have nothing to do with the subject of the conversation, but that he can be very readily brought back again, showing a fairly light and easy grade of fixation of attention which, however, you can see is very superficial. You will notice, furthermore, that his grasp on things is very slight; that whereas he seems to understand what we are talking about it is very evident. that, beyond the merest superficial hold on the subject, it does not penetrate very deeply into his thought processes I have tested his book memory, his ability to multiply and subtract, to write the names of some of the Presidents of the United States, places in New York city with which he is familiar, and find out that his memory of things which have taken place in the past is fairly good, but that, the state of the past is fairly good, but that, for at least a period of six months, his memories are very poor, and are mostly supplanted by the confabulations of which we have already had ample illustration.

We did not notice the presence of any hallucinations. although when the patient at first came into the hospital at night he cried aloud, was uneasy, and gave evidence of having acute hallucinations of sight and of hearing. He was then in a mild state of delirium quite comparable to the

delirium of delirium tremens.

Asking him if he is a heavy drinker, of course he says that he "drinks a little beer, and a little whiskey, well, once in a while," and he finally is made to confess that perhaps he sometimes drinks a little more than he ought, but we learn from his wife that he has been a hard drinker for the past six months and more, and, for days at a time has been drunk.

I next call your attention to his arms and legs. You notice that he is able to extend his wrists with considerable difficulty, that the whole forearm is weak; he has some power to grasp the hand, but you will observe that it is very weak. Examination of the feet shows that there is a mild degree of foot drop, that extension is almost gone, and as we get him up to his feet to walk, he is hardly able to stand, walks with support, with his feet far apart, and the exertion is almost too much for him. His knee jerks.

arikle jerks, wrist jerks, and elbow jerks are all gone.

As I press upon the ulnar nerve, you notice that he winces, although my pressure is very slight. Pressure along the scratic provokes the same painful sensation, and the entire body shows marked tenderness on pressure of the skin and muscles, especially over the nerve trunks. I call your particular attention to his pupils, which you will perceive are unequal, and do not react to light, although they do to accommodation. In other words, this patient shows a fairly typical Argyll Robertson pupil. Let me add that upon his admission, ten days ago, there was almost complete paralysis of accommodation, and that the convergence reaction was very slow. I call your particular attention to the presence of this Argyll Robertson pupil, since you will find it recorded in reliable textbooks that this condition is not found in the disease which we have

A brief recapitulation of this case shows us a chronic drinker who has frequently been drunk and who came into the hospital unable to walk, with the signs of a multiple neuritis and an active delirium associated with hallucinations of sight and of hearing. That after he had lain in a semistuporous condition for a few days, his delirium abated, but instead of making a complete recovery, as many cases of delirium tremens do, we find him passing over into a chronic phase, in which he has some delirium at nights, although otherwise he is quiet and clear. His mood is more or less happy, and his general conduct is all that could be desired. He shows no marked alteration of personality and understands everything that is going on about him.

A physical examination shows unmistakable signs of polyneuritis, severe in grade-not causing complete paralysis of his arms or legs, yet involving

the reflex mechanism of the eve.

Mentally he shows some very striking changes. (I) In the first place there is a definite disturbance of his power of attention. He was not well oriented as to his surroundings, as to time, as to place, although this has improved somewhat. Now, at times, he seems to be correctly placed, and in half an hour later he may be distinctly lost. His sense of time is particularly involved, and he cannot tell within days how long he has been here.

(2) He further shows marked memory defects. A retrograde amnesia which stretches back several months. He has almost no ideas of what he has

been doing for some time past.

(3) To make up for these obvious memory defects we noted that the patient attempted to fill up the gaps by telling us of things that he had done, which were manifestly impossible. This confabulation is promptly negatived by another and then still another, and the patient by suggestion may be led to say almost anything. You may recall how easily one may suggest hallucinations to patients suffering from delirium tremens. This patient thus shows us two definite types of confabulation, the so called opportune confabulation, i. e., an attempt to fill up the gaps in his memory, and the suggestion confabulation already spoken of. Sometimes the patients will show a rich phantasy confabulation, built up largely on a basis of a mild hallucinosis. It is almost a dreamy delirium, similar in type to that which Regis assures us Hercules suffered in Euripides's tragedy of the Mad Hercules. In some instances the confabulation approaches very closely the delusions of grandeur of the paretic. Yet alongside of this active confabulation the patient interrogated with reference to old events is usually pretty clear and orderly. This is not the invariable rule, however, since much depends on how widespread the cortex may be involved in the neuritic process.

Before passing to the history of another case, let me say a few words concerning the general pathology of Korsakoff's psychosis.

Pathology.

The lesions which have been described in chronic alcoholic delirium, or Korsakoff's psychosis, do not differ in any essential respect from those that we know of when studying multiple neuritis; the varying symptom picture depends exclusively upon the distribution of the lesions. Furthermore, it should not be forgotten that, not only is the nervous system very extensively implicated, but that other organs of the body are also involved, so that one has to consider, for the graver cases at least, that Korsakoff's psychosis is a combined result of localized

neurological lesions as well as of a general toxæmia. A complete analysis of the pathological findings in the different cases would be beyond the purposes of this talk. I can only remind you of what I have said with reference to the distribution of the lesions in general paresis; it emphasizes the diversity in the clinical picture and its correlations in pathological involvement.

You will best understand the pathology of this intoxication by assuming the same type of degenerative changes in the neurons which are seen peripherally to be extended into the central nervous system. Thus the changes in the functions of the spinal nerves are to be explained largely by reason of peripheral involvement, and the changes in the psychical functions are due to more or less extensive intraneural disease. I shall again call to your mind the analogy which I outlined in discussing the subject of alcoholism, that alcohol is the great dissociator of function, and in the profound alteration in the psychosis in question we find that organic changes make permanent, to a greater or less extent, these dissociations which functionally are seen in the simpler types of ordinary drunkenness. It can thus be seen that Bonhoeffer, in assuming that chronic alcoholic delirium, which is his name for Korsakoff's psychosis, is practically nothing more than a prolonged and chronic delirium tremens, has not only the weight of evidence of symptomatology, but also the findings of pathological anatomy to support him.

It has only been in recent years that the degenerative changes in the brain stem, basal ganglia, and pallium itself have been subjected to critical analysis, more particularly by the methods of Marchi, Herxheimer, and Nissl. The initial changes are those of any type of acute toxic delirium; they need not detain us. The Marchi method utilized in the early stages of the disease. as Siefert has done in a case dying six days after the onset of the affection through a bronchial pneumonia, shows very widespread degeneration in the fibres of the pallium, the intracortical fibre network, and also the tangential fibres show signs of neuritic degeneration. In Siefert's case, in particular, the fibres of the central lobes bore the brunt of the

degenerations. Heilbronner has also found the same type of degenerative changes in the cortex, particularly in the central lobes, but he has also reported cases of two weeks' duration, and of six weeks' duration without any marked signs of degeneration. This latter finding is not difficult of interpretation, when we bear in mind how great a functional loss may be present without any necessarily permanent organic basis. In the various brains that have been examined an extraordinary amount of variability in the locations of the lesions has been observed, but in all cases one expects to find distinct changes in the fibres of the associated mechanisms, thus accounting for the clinical pictures. On the groundwork of the precise localization of such lesions one is unable on pathological foundation ofttimes to define between a Korsakoff syndrome of senility or of alcoholism. The bloodvessels usually show very characteristic changes. These are usually very widely dilated, and there is a tendency to an increase in the number of

small bloodvessels, somewhat similar to that which has been observed in the new vessel proliferation of paresis, rarely, however, reaching such a severe Hyaline degeneration of the walls is extremely common, whereas many of the vessel walls are thickened and arteriosclerotic. As in delirium tremens, so in chronic alcoholic delirium, there is a tendency to minute hæmorrhagic extravasations. These are found not only in the cortex, but also in the basal ganglia and nerve nuclei, and even in the peripheral nerves. Such extravasations are usually localized along the course of the bloodvessels, and not infrequently give rise to large degenerative masses, thus accounting for the localizing symptoms so frequently observed in Korsakoff's psychosis and in polioencephalitis superior (Wernicke). In this latter disorder it is only necessary that the extravasations should occur in the neighborhood of the nuclei of the eye muscles.

Miliary hæmorrhages are the rule, but occasionally they may be macroscopic in size. Thus in a case of Eisenlohr, a protracted delirium with dizziness, vomiting, and ophthalmoplegia (showing Wernicke's syndrome), there were hæmorrhagic foci in the region of the third ventricle and of the aqueduct at least one to two centimetres in diameter. Bonhoeffer has described a case of Korsakoff's psychosis, which resulted fatally, in which a large hæmorrhagic area was found in the cerebellum.

As a rule the changes are of a noninflammatory nature, but it must be borne in mind that the precise significance of many of the anomalous cells found in these cases has not yet been established. I can only refer you again to Alzheimer's monograph, already referred to, and also to some recent work of Perusinis on the Körnchenzellen done in Alzheimer's laboratory.

Changes in the neighborhood of the nuclei of other cranial nerves are known, and it is highly probable that many of the cases of sudden death are due to involvement of the vagus nucleus. Thomson, Gudden, and Strümpell have reported such findings.

Changes in the spinal cord are no less striking than those in the cortex iself, especially degenerations in the columns of Goll and Burdach. Degenerative changes in the intermedullary portions of the anterior horn cells, in the pyramidal tracts, and the lateral cerebellar tracts, have been described by Heilbronner.

Summarized then we see that a diffuse, severe, destructive process is at the foundation of Korsa-koff's psychosis; that such process involves the entire nervous system very irregularly, including the parenchyma, bloodvessels, the fibres, with the frequent occurrence of small hæmorrhagic foci. Such a process is not pathognomonic for Korsakoff's psychosis by any means; certainly, in the acute stages, the clinical as well as the pathological picture is not distinct from other acute intoxications. However, study may show that the chronic processes are characterized by types of localization not found in other mental disorders, but at best the research involved is time consuming and extremely difficult.

With such a varying pathology, withal so definite, and apt to follow certain trends, the symptomatology becomes all the more interesting to in-

Let me call your attention to another case which you saw in the Bellevue wards about three weeks ago, and which you now find in Ward's Island.

shall be very brief with this case. CASE II .- L. W., forty-two years of age, married, housewife, two children. She had been a moderate drinker for several years, but of late had lost powers of self control and was taken to Bellevue in an attack of delirium tremens,

which was not her first offense She had been having a steadily advancing neuritis for a short time previous to her admission, and while there as you saw her, you will recall an active delirious patient, with hallucinations of sight and of hearing, the former predominating, and yet unable to move her arms or legs, by reason of a flaccid paralysis and with lost knee jerks. tient's pupils were unequal, were sluggish to both sight and accommodation, but there was no marked Argyll Robertson

After her initial delirium she did not clear up as is usually the case-Bonhoffer tells us that about three per cent. of the cases do not, and go on in the manner in which this case has progressed. It is now four weeks since we saw the case in Bellevue while in its delirious phase, which phase is present in from fifty to sixty per cent. of the cases, and in which condition many of the patients die. She still presents the signs of a multiple neuritis, although the paralysis is not so marked as it was, and the indications that she will make a partial recovery at least

The chief interests in her case consisted in the mental symptoms. She had been more or less somnolent throughsymptoms. She had been more of less sommored through-out the time and had shown during the past week unmis-takable signs of asymbolia; i. e., she had not known her-bed, put her clothes on upside down, and did not recognize which clothes were which.

At the present time she speaks clearly but has been para-At the present time site speaks clearly but has been para-phasic and paralexic; even now she reads badly, only partly understanding what she reads. You may recall another patient that I showed you who tried to read with the newspaper reversed. She is badly oriented as to time. Does not know the year, or month, or day; nor can she tell how long she has been here, although she seems perfectly clear superficially. It may be of interest to recall that all of the sensory perceptions may be involved, or, as in a case described by Liepmann, the patient was inattentive to and unable to grasp optic perceptions only.

She has a mild degree of retrograde amnesia, yet you find her comparatively clear for events which antedate her last drinking bout. Her memory for recent events is very bad. She cannot remember anything ten minutes. What she had for lunch has gone from her recollection.

You noted an interesting feature of her confabulations,

She was all the time talking about her children. She told you she had been playing with them this morning, and was apparently in a comparatively happy mood notwith standing her deplorable condition. She gave a number of pseudoremissences regarding her husband and children. The type of confabulation here was of the opportunity type, rather than of the suggestive variety which we saw in another case, J. K. You noted she was less liable to take hold of my suggestions, but wandered on in a sort of fantastic dream about the children

food of my suggestions, our wantered on me a soft of fair-tastic dream about the children.

For the past week the patient remained apathetic, and had no initiative. As in our other case, it was possible to gain her attention quite easily, and the quick response gave one the idea of an active intelligence, but you noted the attention soon wandered, and in the wards she was never able to go on with anything she started to do. There was a distinct difficulty in her ability to grasp ideas. There was no change in the patient's ability to reason on ordinary topics; than the patient's abinty to reason on ordinary topics; her personality was not altered, and beyond the memory defects, and the confabulation, she seemed well mentally. Her mood was for the most part happy, but toward evening she was apt to get anxious, and at times cried very easily.

Permit me new to call your attention to the neuropathological disturbances which may occur in Korsakoff's syndrome. The cases which I have

shown you exhibit a number of anomalies to be noted, but you are probably aware-from your work in neurology-how very extensive, and vet how variable may be the changes in multiple

Cranial Nerves.—So far as changes in the sense of smell are concerned there are no observations on

The optic nerve is frequently involved. There may be a temporary or a permanent optic neuritis. Wernicke has recorded retinal changes similar to those found in acute hydrocephalus. Optic neuritis with hæmorrhage has been observed, and irregular pupillary pallors are frequently seen. Central scotomata to certain colors, a not infrequent picture of the neuritis retrobulbaris, has also been found.

Inasmuch as there seems to be no doubt that a true optic neuritis may be seen accompanying Korsakoff's syndrome it behooves one to be on one's guard relative to the distinctive diagnosis from tumor, for instance, abscess, or meningitis. occurrence of a temporal pallor, reported by Bonhoeffer, Oppenheim, Strümpell, and others should be borne in mind in the distinctive diagnosis from multiple sclerosis.

Pupillary disturbances are so common as to have been recognized by almost all observers. Dreschfeld, Kiefer, Gudden, Möli, Thomsen, et al.

It is peculiar, however, that little mention of them is made in English literature. White is practically the only American author who notes them. pupils are frequently unequal. The reaction may be slow; there may be true Argyll Robertson pupil, or there may be paralysis of accommodation. Oppenheim has reported such a case," and I have had one in my service at the City Hospital showing the phenomenon, which cleared up in about four weeks. Myosis is the rule, the pupils being very small. Nonne, however, speaks of a case with marked dilatation of the pupil. I have seen several cases in the Bellevue psychopathic ward, especially in patients suffering from the initial delirium.

Weakness of the eye muscles is common, the abducens seeming to suffer more than the others. Nystagmus is not rare, and ocular palsies not infrequent. In view of these complicating eye symptoms it may be seen at once that the distinctive diagnosis from paresis, or Wernicke's polioencephalitis superior comes into review. In the presence of disturbances of associated eye movements the diagnostic difficulties become even more acute.

Pain in the trigeminus is not rare.

Speech difficulties are very frequent. They are complex in causation. The facial, hypoglossal, and subcortical innervation may be severally involved. Bonhoeffer (l. c.) states that difficulties in tongue movements are common. This is my own experience. Roth¹³ and Kast ¹⁴ report lingual atrophy. Such findings are rare.

The facial nerve is not spared. Whereas its im-

plication is not an infrequent accompaniment in multiple neuritis without mental involvement, it seems to be rare in Korsakoff's syndrome. Knapp, in his recent monograph, states that he has never observed it. Paralysis of the soft palate has been seen by Bonhoeffer. Ptosis is not infrequent.

The vagus is frequently implicated; pulse anomalies being exceedingly common. Cyanosis, tachycardia, a characteristic dyspnœa, and short breathing indicate its disturbed action. Frequently the pulse runs up to from 120 to 130, while Knapp (l. c.) reports cases of vagus irritation, the pulse dropping to 38 beats to the minute, accompanied by marked reduction in temperature.

Bulbar symptoms, difficulty in swallowing, etc.,

are rare, but have been observed.

So far as the upper extremities are concerned, they are less frequently involved than the lower. Pain, paresis, or paralysis with atrophy, especially in the distal portions, are to be expected, and there

is frequently marked ataxia in the arms.

The lower extremities are usually more severely implicated. The gait is frequently widespread, or halting, occasionally steppage; rarely it shows the cerebellar swaying. Occasionally it is typically tabetic in character. The peronei are most often involved, although Knapp's experience points in other directions. The quadriceps are also implicated, Bonhoeffer says, as frequently as the peronei. The knee jerks are usually lost, although in a few anomalous cases they are increased, and Knapp reports a case of ankle clonus.

I have already alluded to a case with quadriceps paralysis, the peronei remaining comparatively

active.

The sensory and trophic disturbances are in accordance with what is known for alcoholic neuritis.

The bladder is not infrequently involved.

It may thus be seen from these symptoms that a distinction from tabes dorsalis may be necessary. Symptomatically this may be impossible in the early stages. Furthermore, the two conditions may co-exist

Temperature depression is the rule. This may be due, says Knapp, to an involvement of the vasomotor centres in the medulla. This depression may exist for months, the temperature remaining about 95° F. for all this time. Such subnormal temperatures are noted in cases of mental disturbance associated with brain tumor, and abscess, and in paresis. Other vasomotor disturbances, such as transitory cedemas, transitory erythemas, are of occasional

Focal Symptoms.

Certain focal symptoms are of particular interest. In discussing the pathological findings I called attention to the changes in the brain stem and subcortical ganglia and to degenerations in the fibre tracts of the cortex. I spoke of the hæmorrhagic foci that occasionally were present, and also inferentially called your attention to the fact that oft-times the degenerations in the fibres themselves were clustered or concentrated, so as to form pseudofocal lesions. In many of the chronic cases we have to consider the focal symptoms as largely due to such concentrations of the diffuse degenera-

tions present throughout the brain area. Some of the more important neurological symptoms remain to be discussed.

Speech.—Those of speech are perhaps the most striking. So called stuttering speech of chronic alcoholism, especially in the delirious, is frequent. Korsakoff himself, in his original description, which I have already given you, called attention to it. Such speech disturbances may be of purely cortical origin, although Bonhoeffer is inclined to think that

they are mostly bulbar.

Motor aphasia.—This has been observed in a number of instances, in fact, many cases of profound Korsakoff's psychosis usually seem to show a motor aphasia. It is of the transcortical type, however, which has been called by various authors a pseudoaphasia (Tiling), a parakinetic aphasia (Knapp), sensory aphasia (Pick), Bischoff, Liepmann, Bonhoeffer, Wernicke, Gudden, have all reported cases in which sensory aphasia of greater or less degree

has been observed.

It is natural that in a disorder showing such diffuse changes in the cortex the sensory apparatus should be involved. Knapp has reported a case of word deafness, Bonhoeffer several cases of paraphasia; amnesic aphasia and echolalia are known.

Reading disturbances.—Many cases of Korsakoff's disease showed marked disturbance when reading; false words are read, many small words left out or frequently interjected. Knapp has suggested the term "confabulatory reading disturbance" for the most typical of these changes.

Disturbances in writing are equally present. Perseveration, incoherence, verbigeratory writing are common. Patients very frequently write their names over and over again, and the same character of confabulatory feature may be present in the writing as in the speech or reading. Bonhoeffer has reported a case of sensory aphasia agraphia.

Apraxia.—Liepmann's ideatory apraxia is not infrequent in this disorder; such cases have been recorded by Liepmann, Knapp, Gudden, Wernicke,

and Bonhoeffer.

Transitory homonymous hemianopsia, word blindness, soul blindness, cortical taste paralysis, asymbolia, agnosia are among some of the rarer disturbances observed.

In a number of cases epileptiform attacks, which may be unilateral or bilateral, occur. These are very frequently associated with an active delirium, are accompanied by unconsciousness, and in most respects resemble an epileptic convulsion. Apoplectiform attacks occur less often although pseudoapoplectiform attacks are by no means rare.

Clinical Forms.

I have said enough to indicate that great variability exists in the general clinical form in these patients. Truly speaking, the erection of hard and fast types is more or less pernicious in such a kaleidoscopic affection, yet certain trends or tendencies of development are worth recording. This I shall do, telling you the forms described by two authors who have made special studies. Dupré, who in Paris sees all of the prisoners of that large city suspected of any mental disturbance, has written, in the textbook already cited, an excellent

résumé of the disease. He gives five clinical forms: (1) Amnesic form, in which the profound involvement of the memory stands in the foreground. (2) Confusional form, in which the mental haziness remains, the patient remains heavy and stupid, speaks slowly, vaguely, and hesitatingly; is inert, indifferent, unstable, undecisive, and anxious. (3) Delusional form. Here the patient shows a characteristic dreamy delirium. The combination of loss of memory, mental confusion, suggestive hallucinations, loss of critical power, automatic pseudosensory dreaminess-makes the patient carry on a line of capricious and incoherent waking life. The patients are frequently attacked with delusions of persecution; or have ideas of negation, or of a depressed hypochondriacal type. These are usually fleeting conditions, but may form the basis of a secondary systematized delusional state. (4) Anxious form, characterized by the predominance of ideas of disquietude, of anxiety, of panphobias, and active emotional reactions. Emotional paroxysms usually are worse at night. The depressions are largely affective rather than intellectual. (5) Demented form, in which the major trend is toward marked intellectual enfeeblement. The asthenic and typhoid types of this form usually lead to a more or less rapid death.

Knapp's monograph, already cited, distinguishes: (I) Delirious form, which is present in the beginning at least of two thirds of all patients with this psychosis. (2) Stuporous form, quite comparable with Dupré's Confusional Form. (3) Demented form. (4) Hallucinatory form with hallucinatory excitement and hallucinatory confusion, without any systematization of false ideas. (5) Hallucinatory form with systematization, quite comparable with Wernicke's acute hallucinosis. Ideas of reference and anxiety producing hallucinations are frequent. Ideas of injury arise, and ideas of persecution are not infrequent. The confabulation in these patients is filled with ideas of injury. Many of these cases are diagnosticated as paranoias, especially if the neuritis is comparatively mild. (6) Paranoid forms with episodic attacks of delusional interpretations or pseudoreminiscences of being persecuted. Illusions are not infrequent, and the patients are continually explaining their sensory perceptions by the delusional assumption of external ideas of influence. Ideas of reference and of injury are frequent; being electrocuted, magnetized, etc., are not infrequent; being hypnotized by their enemies they are unable to walk, etc. (7) Anxiety forms. (8) Expansive forms, in which ideas of grandeur appear in the confabulations. These cases are frequently diagnosticated as cases of paresis, and enter into the statistics of some physicians as "cured cases of paresis." (9) Manic and melancholic forms. Such are rare. (10) Polyneuritic motility. rare. (10) Polyneuritic motility psychosis of Wernicke is a type well recognized by those acquainted with Wernicke's teachings. It is a melange with characteristic motility changes, into which we cannot enter here. (II) Anomalous forms with irregular psychical anomalies. Some patients show impulsive ideas; others a peculiar foulness of thought-obscenities constantly obtruding themselves upon them-others show typical Vorbeireden.

Diagnosis.

Little, in addition to what has already been said, need be taken up in the discussion of the diagnosis. The chief danger point is the elimination of general paresis, and mistakes may occur either in the prodromal period, during the acute initial state, during the chronic stages, in which the patient's disorder remains stationary, or in the terminal phases.

Irregularity and excessive mixture of symptoms with bizarre groupings make one think of paresis rather than of a Korsakoff, but it should not be forgotten that there are a number of cases of true paresis which run a course very similar to that of a Korsakoff, so that not only is it essential that one should not mistake a Korsakoff for a paretic, but the obverse is true, although less liable—one should not falsely diagnose a paretic as a Korsakoff. Naturally the use of spinal puncture and the cytological examination of spinal fluid has cleared up a number of the difficulties with which psychiatrists formerly had to deal, and has given a precision which has heretofore been lacking. The Wassermann-Plaut serum reaction should also be tried in all doubtful cases.

In the acute delirious stages, Korsakoff's psychosis may be mistaken for a number of things, and it is practically impossible to state with certainty just what the condition may be. Thus the distinction of Korsakoff's delirium from a recurrent delirium tremens or a polioencephalitis hæmorrhagica superior may be impossible. In the stuporous forms and apoplectiform forms, acute internal hyprocephalus and meningitis may have to be borne in mind.

Course.

The course of this disorder is extremely variable. Many patients, following the acute delirium, enter into a chronic, stuporous state, and die in from two to three weeks; others go on in a less stuporous apathetic condition, gradually growing weaker and weaker, and at the end of three or four months die. These patients frequently show the accompanying effects of disturbance of the liver and kidneys. There may be ascites, ædema, albuminuria, etc. Some patients die of quickly developing miliary tuberculosis.

A comparatively large proportion gradually recover from the effects of the acute delirium and go into different stages of restitution. The grade of restitution is impossible to tell in advance.

The age of the patient, the number of attacks of delirium tremens, the physical condition, the cause of the neuritis, whether alcohol or one of the many other causes—all these determine in some measure the outcome.

It may be said that but few patients make a complete recovery. A number make such recoveries that only a skilled observer can detect the impairment, but impairment in some degree usually persists. Still, after a number of years of careful treatment, in patients who may be carefully treated, a restitution ad integrum may be posited.

The most frequent cures are those in which only a slight intellectual weakness persists. The amnesias clear up, but the patients remain more or less incapable of sustained, efficient effort. They may become good dilletantes in intellectual pursuits, but rarely accomplish much. Every patient is worth

working for, however, and when defects are found to exist, psychological pedagogy may be interested to repair the defects by building up associations in heretofore unused tracts which presumably have not suffered any loss.

Treatment.

The treatment differs but slightly from that which you already know to be laid down for multiple neuritis. The preliminary indication is to allay irritability as much as possible, further treatment should retard degeneration, conserve function, and finally aim to educate the damaged organ to better working. In order to allay irritation, hot baths are useful, both to control the delirium, and to limit the pain; hot packs may be used if a hot bath is not at hand. Other eliminative measures in addition to heat should be encouraged for a certain time. Thus fair catharsis and active diuresis should be encouraged, since there is a marked tendency for serous extravasations, which may be even hæmorrhagic, into vital centres, and it is essential to keep the blood pressure within normal limits. usually best accomplished by heat, but it may be necessary to keep the internal and external capillaries fairly well dilated by pressure reducing drugs -drugs that cause excessive vomiting are preju-

It is highly important that the nutrition of the patient be maintained. Overfeeding, as soon as the stomach will permit, is a *sine qua non* in the treatment of Korsakoff's psychosis, which overfeeding should include a high percentage of fat. Milk, butter, and eggs are the most palatable of these foods.

Whether there is any direct lesson to be read from the teachings of Meyer and Overton concerning the relationship of fat and alcoholic absorption I do not know, but it seems reasonable that if the absorption of alcohol in the nervous system stands in more or less direct relation to the solubility of the alcohol or other narcotic in fat, that one should bear this word picture in mind, and realize that fat destruction is an integral portion of the pathology of Korsakoff's disease.

Whether other forms of fat producing food would be better than those that I have mentioned I do not know; that is one of the problems of construc-

tive metabolism.

The neuritis needs to be treated by methods with which you are undoubtedly familiar, massage, elec-

tricity, and strychnine.

As to the training of the memory, little progress has yet been made so far as the acute stages are concerned. The patient's grasp of things is so slight and so evanescent that applied pedagogy will bring its own reward in loss of time and effort; but later on in the course of the affection a true scientific pedagogy may need to be called upon, especially if the defects observed are more or less localized. If it is found, for instance, that the patient's optical memories seem to have borne the brunt of the storm and have been left with reduced capacity it may be desirable to apply the principles of a constructive education to other less affected receptors or their connections. In these cases each patient is naturally a law unto himself, but there is little doubt that many cases of Korsakoff, which seem to be helpless, and which go on to a terminal dementia for lack of initiative on the part of the physician to search out what part of the mechanism may still be utilizable, might be helped if the principles of scientific peda-

gogy could be applied.

In the actual treatment of these patients, after the neuritis has recovered to such a degree as to permit of a more or less free going about, occupation cures promise the most. For the more well to do, outdoor games, horseback riding, golf, swimming, are desirable. Carpentry, blacksmithing, bookbinding, or even manual labor on a farm, or training in the open, is advisable.

One principle should not be forgotten in all your therapeutic efforts, and that is not to overdo them, bearing in mind that excessive physical work calls for an amount of nervous functioning just as mental work, that no adaptation to hit even a golf ball correctly can be carried out without an immense amount of nervous functioning, and that therefore in the earlier stages those games or occupations should be chosen which do not call for a high degree of nervous tension—such as the lazy lolling about of swimming—and that no exercise treatment should be overdone. Hard muscles, ruddy cheeks, ability to run twenty-five miles after a dog cart, these may be the delusive signs of a healthy musculature at the expense of mental restitution.

Naturally I need not insist upon the avoidance of all tonics which contain alcohol in any form, especially such tonics as peruna and the ilk, some of which I have known to be responsible for the de-

velopment of Korsakoff's psychosis.

64 WEST FIFTY-SIXTH STREET, NEW YORK.

DIAGNOSIS OF ERYTHEMATOUS AND EXAN-THEMATOUS RASHES.*

By Charles A. Kinch, M. D., New York,

Dermatologist to New York City Children's Hospitals and Schools; Clinical Assistant to New York Skin and Cancer Hospital, and Lebanon Hospital.

The dermatologist approaches his cases in a different attitude from the internist. The physician asks his patient "What is your principal complaint?" and "How long have you been ill?" He first gathers up the history and symptoms, and striking a balance makes a provisional diagnosis. He then seeks for the physical signs and revises or confirms it. The specialist says: "Have you something the matter with your skin? Take off your clothes and let me see it." The lesions being all upon the surface, he is taught to "look and say." Having made his diagnosis, he may inquire into the history. If that is corroborative, all is well. But if not, it has been said "so much the worse for the history."

An eruption well described can often be recognized by the specialist without seeing the patient. Dermatology has a patois of its own, and at the risk of being tedious, and of reviewing what you already know, I will recount briefly the common lesions of

the skin.

The color of the skin is a combination of the creamy white of the connective tissue, the brown pigment in the epidermis, and the varying shades of

[&]quot;Read in part before the Medical Society of Westfield, N. J., April 7, 1908.

the blood in the dermal capillaries. The blood may vary from pale to deep scarlet, to crimson, and on

through the purples to bluish black.

A localized change in the color of the skin without swelling is called a macule. Macules are usually pinhead to lentil sized, though they may be as large as a dime. They may be due to an increase of the pigment, of which a familiar example is freckles. But more often there is a change in the circulation and dilatation of the papillary loops as is seen in scarlet fever, measles, and the indigestion and drug rashes.

If now there is a spasm of the muscular coat of the dermal vessels, there will be a whitish elevated spot surrounded by a red border. These lesions are called wheals, and commonly follow the bites and stings of insects. On sensitive skins they may be seen after the use of the hypodermic needle.

A thickened spot in the skin is called a papule. There is a deposit of plastic exudate in the true skin. These elevations can be felt by passing the ends of the fingers lightly over them. And if the skin be stretched they do not disappear. Larger infiltrations involving deeper structures are called

tubercles.

A droplet of serum separating and elevating a portion of the cuticle forms a vesicle. Large vesicles are called blebs or blisters. Vesicles are often surrounded by a red border. They may be single or multilocular. The layers of cuticle covering them may be few and thin, in which case they rupture easily, or the walls may be thick and firm.

Small collections of pus are called pustules. They may come from changes in vesicles or they may

arise de novo.

Small hæmorrhages into the skin are called petechiæ, and if they are arranged in straight lines are called vibices.

Many diseases are accompanied with increase in the horny layer which is later thrown off in scales. The process is called desquamation. If the scales are fine and branny it is furfuraceous. If the cuticle comes off in large flakes, the desquamation is lamellar.

An inspection of the visible mucous membranes affords valuable assistance in the diagnosis of many eruptions. Of course the most convenient are those of the mouth and throat. The anatomy of the mucous membrane is similar to that of the integument. Only the horny layer is lacking. Owing to the absence of this protective layer the vesicle soon becomes a superficial ulcer and the papule a mucous patch.

Macular Eruptions.

Suppose now a patient is brought before you, a well nourished boy of five years, covered with a brilliant and finely punctate rash, more abundant on the trunk than on the face, the nates and parts subject to pressure of a uniform redness, in other places the intervening skin slightly ædematous and of a yellowish color. The child has a high fever and a rapid pulse. The submaxillary glands are enlarged. The tonsils and uvula are much swollen and bathed in transparent mucus. The color of the fauces is livid, and there are a few punctate maculæ on the roof of the mouth. There is a singular absence of the eruption from the central part of the face pro-

ducing a white ring about the mouth that is pathognomonic. The diagnosis is scarlet fever. The tongue is coated with a white fur through which some of the larger papillæ show. This is not the "strawberry tongue." A few days later in the disease the epithelium will be shed from the edges of the tongue leaving a bare surface with a crenated or scalloped border, the convexities toward the centre. These denuded areas are red in color and the swollen papillæ give them a striking resemblance to a red raspberry or strawberry. The exudate upon the tonsils will also become cloudy from the admixture of white blood corpuscles, and the physician then is apt to think that diphtheria has supervened. One must not forget, however, that diphtheria does often complicate scarlet fever.

Suppose now another case. A girl, twelve years old, has a punctate rash on the neck and hands, no fever, no angina, no change in the buccal mucous lining, no adenopathy. A slight ædema of the hands causes some stiffness and a feeling as if they were encased in tight gloves. No eruption on any other part of the body. She has a simple erythema. It is very difficult to distinguish between this harmless eruption and mild cases of scarlet fever. The resemblance is so great that sometimes it has the right to be called scarlatiniform. Some cases may be held in suspicion for three or four days until we are sure that no angina will develop or desquamation follow. In this connection may be mentioned erythema multiforme, which is more general in its distribution, presents a greater variety of lesions, and may be accompanied by nodular swellings on the extremities. There may be slight fever and a coated tongue. It seems to depend on autointoxication from retained fæcal matter.

Suppose again, a fair blonde child of four years, with flushed cheeks, a scarlet macular eruption irregularly distributed over the body, pinhead to lentil sized and somewhat itchy. There may be redness of the faucial arch. On inquiry you will learn that the child had symptoms of a cold and had been given medicine to break it up. If the family believe in regular practice, it was quinine or antipyrine. If of the homocopathic persuasion, it was belladonna, either with or without aconite.

After the injection of antitoxine a rash appears in one half the cases. It usually begins near the site of the injection and spreads in all directions. It may be macular erythematous in type, or may be in small wheals, urticarial. In the latter case it is very itchy. Papular urticaria from other causes

may also be mentioned in this connection.

Suppose now a young woman, with a rose colored, macular, lentil sized eruption, which has come out suddenly overnight on the face and is spreading over the body, with a fever of 102° F., malaise, headache, and backache. She has slight coryza and conjunctivitis. The fauces are injected, and the macular rash is reproduced on the soft palate. The tongue is coated, red papillæ showing on the edges. The submaxillary glands are not much swollen, but those of the posterior cervical chains are notably large and tender. The epitrochlear, the axillary, and the inguinal, both of the groin and Scarpa's space, may be involved. The macules vary in size from a pinhead to a small bean. There is a slight

ædema of the spots giving them a papular appearance especially on the forehead and around the mouth. She has rubella, or German measles. When the larger macules preponderate, the rash resembles true measles; when the smaller, scarlet fever. It is the latter, or punctate, form which has been recently described by Clement Dukes as the "fourth disease."

Let me conjure again and bring up a sturdy boy of fifteen years. He has a high fever (104° F.), coryza, conjunctival injection, and photophobia, and an extensive erythema of the upper lip. He coughs incessantly, is hoarse, and complains of dryness of the throat. The tongue is heavily coated, the fauces deeply injected, the palatal and buccal mucous membranes covered with a partially diffuse crimson eruption in which appear faint, blue white dots. On the sides of the neck an irregular lentil sized, crimson, macular eruption is visible. He is coming down with the measles.

The next patient is a man with a coffee bean to filbert sized macular eruption on the face and trunk. Its color is crimson to purple. The macules are darkest in the centres with the edges fading off into the natural skin. It does not itch, and it has come out rather suddenly. There are dark circles under his eyes, and the patient complains of wakefulness and headaches at night. His hair is falling out. The submaxillary glands are much swollen and of a stony hardness. The adenopathy is general. There is a small ulcer with a hardened base on the border of his lower lip, which has persisted for two months, and he cannot get it to heal. This man has syphilis in the early secondary stage. Acquired innocently, the initial lesion being on the lip.

At a subsequent visit he brings with him two friends. Their record is not so clear as his. They have been dallying with the demimonde, and fear they have contracted some dreadful disease. One of them shows on the anterior fold of each axilla a cluster of lentil sized, brownish spots with some discoloration extending over the shoulders, and several other spots from a dime to a half dollar in size scattered over the sternal and hypochondriac regions. On the back are similar lesions. By scratching, fine branny scales can be detached, leaving sound skin underneath. He has no venereal trouble. The discoloration is due to tinea versicolor-the growth of a minute fungus upon the skin.

The other friend has a bright crimson macular eruption, pretty generally distributed, sparsely on the face, abundantly on the belly and hips. Here and there can be discovered little wheals on the macules. It itches. He has no fever, no enanthem in the mouth. The inguinal glands are enlarged, and there is a purulent discharge from the meatus urinarius. He has acute gonorrhœa, and has been taking copaiba for its relief.

The next patient is a young man of blonde complexion, with rosecolored dime to nickel sized macules widely scattered over the trunk, oval in shape with the long axes at right angles to the axis of the body. There are slight polar elongations of the red border. The centres are fading to a tawny color. The spots are covered with very fine branny scales. For a few days back he has had slight fever, lassitude, and loss of appetite, and then this came

out. He has a comparatively rare disease, occurring in the spring and fall, called pityriasis rosea.

Our next patient is a young woman with a very high fever, inflamed eyes and throat, headache, and severe pains in the back extending through the waist and much gastric disturbance. A broad band of diffuse erythema covers the middle part of the face. on either side of the nose and around the mouth. A crimson macular eruption is most prominent over the lower part of the abdomen and the inner surfaces of the thighs. She is menstruating, and the flow has come on a little before the expected time She has smallpox, or varioloid, in the beginning of the period of invasion.

Papulosquamous Eruptions.

Of papulosquamous eruptions I shall present three cases. The first is that of a young married woman of a blonde, nervous type, who has distributed over her shoulders and breast, lentil to half dollar sized scaly patches, with well defined borders. The scales come off in flakes that are greasy, leaving tender, reddened skin beneath. She has been troubled with dandruff for a long time, and parts of the scalp will be seen shedding the same greasy scales. She has seborrhœic dermatitis.

The second patient is a young girl with lentil to nickel sized scaly patches, irregularly distributed over the body and extremities. The face is free, but she has a few in the borders of the hair, some of the larger ones have partially healed leaving segmented or complete circles. Confluent patches are present on the knees and elbows. The scales are dry and silvery, and when removed leave a thin pellicle, which sometimes bleeds. She has psoriasis.

The third patient is a young man in the pride of youth. Rather sparsely distributed over his body are lentil to pea sized papules, hard to the feel and of a brownish color. Many of them are surmounted with white scales. Some are grouped in segments of circles. There is a distinct infiltration of the skin of these papules. He has deep ulceration of the tonsils and mucous patches on the edges of the tongue and inside the lips. All the superficial lympathic glands are enlarged. It is syphilis in the second period of the secondary stage.

Vesicular Eruptions.

A woman recovering from pneumonia presents the whole chin swollen and tender, with a number of yellowish crusts. Some of them are blackened by the admixture of a drop of blood. A few vesicles can be made out on the border of the affected area. The inner surface of the lower lip has a few superficial ulcers, yellowish in color, surrounded by a narrow ring of red. Others are grayish. This is an outbreak of herpes febrilis.

A child with a vesicular eruption irregularly distributed on the face, forearms, and hands. The spots, which are pea to nickel sized, tend to spread peripherally and heal in the centre. The vesiculation is superficial and ruptures easily, covering the spots with yellowish crusts. The secretion is inoculable, both on the patient himself and other persons. The disease is contagious impetigo.

A girl, of eight years, has a polymorphous eruption scattered over the body. A few lesions appear on the face and scalp. Some are rose colored, lentil sized macules. Some are bean sized, oval in shape, surmounted by vesicles, filled with a clear serum. In a few the contents are cloudy. Some have finished their course and are replaced with black crusts. The traces of vesiculation appear on the soft palate. She has chickenpox.

A girl, of ten years, complains of great pain and lameness in the front part of one thigh. Examination shows little groups of vesicles quite firm and very painful, distributed over the skin, supplied by the middle cutaneous branch of the anterior crural

nerve. She has zoster.

A boy, of five years, has a papulovesicular eruption, pretty generally distributed over the nates and Simon's triangle, which includes the lower part of the abdomen and inner surfaces of the thighs. Lesions are also found on the anterior folds of the axillæ and the flexures of the elbows and wrists. They are mostly pinhead papules with the heads torn off and replaced by blood crusts. Here and there are vesicles. On the genitals they take the form of shotty papules. He has scabies. Careful search may discover the furrow of the itch insect, looking like a short, black thread in the skin, and you may be fortunate enough to dig her out from the bottom.

Pustular Eruptions.

A boy of eight years has pea sized lesions irregularly scattered over the face, hands, and body. Some are filled with pus and stand up prominently from the skin. They may have a narrow, red border. Some have ruptured and are covered with a loosely adherent, light greenish crust. Others are covered with a thick black crust, easily detached and leaving a raw surface. He has impetigo.

A young man has papulopustular lesions scattered over his face and scalp and pretty generally over the body. They are lentil to pea sized. Some are filled with a clear fluid and have a dimple in the centre. Others are round and full, and the contents are gray or yellowish in color. All have hard bases. And as we rupture them with a needle but a small part of the fluid escapes. They are multilocular. His voice is husky, the fauces are injected a deep red, and there are small ulcers on the roof of the mouth. The soles of his feet hurt him, and there are imbedded in the thick epidermis of the palms and soles, thick lentil sized black crusts. He has a little fever. Last week he was quite sick for a few days and thought he was going to have the grip. He has been vaccinated, but it was several years ago. He has varioloid, and we report him to the board of health.

This occasions some excitement in the neighborhood and our attention is called to another young man. He has a papulocrustaceous eruption also distributed over his face, scalp, and body. The lesions are pea to dime sized, and covered with very thick crusts. The palms of his hands are sore. There is in each palm an exfoliating bleeding tender patch the size of a quarter. He has mucous patches in the mouth and throat. There is general adenopathy. Much of his hair has fallen out, and the back of his head presents a singular moth eaten or plucked out appearance. He has syphilis, and his case is not reportable, though perhaps it ought to be.

Hæmorrhagic Eruptions.

A woman, forty-two years of age, shows on the legs and about the knees and on the backs of the thighs dark red and purplish spots which do not disappear on pressure. Some of them are fading and have a greenish color. They are pinhead to lentil sized. The patient is anæmic, emaciated, and overworked. She had a few days of malaise last week with chilly and feverish sensations and pain in the larger joints. But these symptoms have mostly disappeared. She has simple purpura.

The other cases are too serious to come to the clinic, and may be seen in the hospital. In one of the reception wards there is a thin man with pale lips and dark circles under his eyes, and bronzed patches on his cheeks and neck varying in size from that of a finger nail to a quarter dollar. He is thirty-two years of age. On the arms and legs and loins are a number of hæmorrhagic spots, lentil to finger nail sized. A few are recent and dark blue in color. The older ones are fading and are of all shades of green, orange and yellow. On the calves of both legs and on the right side just below the axilla are large, brownish discolorations with desquamation. The subcutaneous tissues are thickened and hardened, almost boardlike to the feel. These areas have been painful but are not so now. On the flexor surfaces of the forearms and thighs, the skin is roughened like goose flesh. In many of the petechial spots can be seen a central hair. The gums are swollen and spongy with an intense red line next to the teeth. Here and there are small patches of greyish membrane. The teeth are very sore, and some of them are loosened. The gums have receded from them in many places. The remainder of the buccal cavity is pale. The man has hæmic murmurs. He becomes breathless on exertion and is lame from the swellings in his legs. He is recovering from scurvy, and his history is a tragic one. He was first mate on a steamer homeward bound from India with a cargo of teak wood. His vessel was wrecked in mid-Atlantic in a severe storm. The rigging was carried away and the funnel stove in. Her stores were badly damaged. As soon as the storm subsided, the crew seized the boats and were never heard from afterward. Four men were left on board. The wreck drifted about for a long time, never coming within hailing distance. Finally she was reported as a derelict. Meanwhile the little crew had sickened of scurvy and two faithful fellows succumbed one after the other. The captain also took pneumonia and became delirious. The only redeeming feature was fair weather. Then a tramp steamer with a light cargo came near and sent a boatload of sailors to board the derelict. The captain died the same night, but the first mate and the cargo were brought to New York.

In another ward lies a young woman with a high fever and great prostration. Though somnolent, she can be roused, but does not always give a coherent answer. She is a brunette, with heavy black hair, and the congestion of her face gives her complexion a mahogany tint. Her eyes are bloodshot and watery, and black sordes are on her lips. On the neck and chest there is a macular, crimson eruption resembling measles, but with no tendency to

assume a crescentic outline. On the folds of the axillæ and the abdomen are irregular pinhead to lentil sized, brown spots which do not disappear on pressure. They are also on the dorsal surfaces of the wrists. Some of them are livid and resemble purpura. She has typhus fever. She is a Hungarian by birth, and after five years residence in this country, paid a visit to her old home. On her way back, she visited friends in London and sailed in company with some of them. One was taken with a chill on the day of landing and detained at Ellis Island Hospital. Three days later she was attacked in the same way.

The last patient is in the isolation ward, and we may look at him through the observation window in the corridor. He is a young and well nourished man of about twenty-eight. His face is crimson and swollen beyond recognition. Dark hæmorrhagic circles surround his eyes, and ecchymotic spots are seen in the conjunctivæ. His nostrils and mouth are stained with blood, for he has hæmorrhages from those orifices. He has a troublesome cough, and the sputum is bloody. The tongue is swollen and white, contrasting strangely with the dusky countenance. On the arms and thighs are dark red and purplish spots which do not disappear on pressure varying in size from a lentil to a half dollar. On the trunk and legs are larger discolorations of irregular outline. formed by the coalescence of similar circles. Hæmorrhages have occurred from the bowels. He has no fever, but his pulse is rapid, and there is great depression. Yet withal his mind is clear and will be till near the end. His case is one of purpuric, or black, smallpox. This is the fourth day of his disease, and he can not survive more than one or two days longer.

Nothing has been said about eczema in this paper. This is so varied in its manifestations that it would require an evening by itself. It may be erythemaious vesicular, weeping, papular, pustular, or squamous. These are not different forms, but stages of the disease, and it may pass quickly from one to another.

273 WEST SEVENTIETH STREET.

A SUMMARY OF THE RESULTS OBTAINED BY THE X RAY TREATMENT OF EXOPH-THALMIC GOITRE.*

By G. E. PFAHLER, M. D., Philadelphia.

In the preparation of this paper I have made a hasty review of the literature upon the subject. I have omitted from this report any reference to simple goitre. This review convinces me that the Röntgen rays deserve a more prominent place in the treatment of exophthalmic goitre than they have heretofore received. The reports have been made by well known and careful observers and therefore deserve consideration. Since "results" form the main topic of discussion, I have made little reference to the technique. Most of the reports have been made in 1906 and 1907. Williams (The Röntgen Rays in Medicine and

Read in a symposium upon exophthalmic goitre before the Phila delphia County Medical Society, September 9, 1908.

Surgery, 1902) noted marked improvement in a case after five exposures in about three weeks' time.

Pusey (The Röntgen Rays in Therapeutics and Diagnosis, 1903) reported a case which after mod-

erate exposure showed effects.

Dr. Thrush and I on February 14, 1906, reported before this society a case of exophthalmic goitre (Therapeutic Gazette, March 15, 1906). This patient was a married woman, thirty-six years old, who had noticed the swelling of the neck about two months previously, but during several months before the goître appeared she had noticed restlessness, insomnia, twitching of the muscles of the lower extremities, and a peculiar sense of oppression in the chest as if drowning. About a month before the goitre appeared, she had a spell of some kind, after which she was unable to see for an hour. She had distinct exophthalmos. She was treated three times a week, and after a month there was distinct improvement, both in the general condition and in the reduction in the size of the gland. The improvement continued for three months, when she appeared to be well. Her pulse had been reduced from 120 to 72, and she had gained 25 pounds in weight. At the time of that report I had only found three (incomplete) reports of cases treated by the Röntgen rays. This woman was well when seen a year later, and a letter states that she has remained

One of the best reports made upon the subject is that by Freund (Münchener medizinische Wochenschrift, 1907, Nos. 7 and 22). He reports five cases. Three were treated exclusively with the Röntgen

Case I.—Patient was a woman, thirty-four years of age, who had symptoms for eight weeks. She had an enlarged who had symptoms for eight weeks. She had an enlarged left lobe of the thyreoid, pigmentation of the skin, and the pulse rate was 120. There was an increase in cardiac dullness to the left, and a systolic murmur. Stellwag's symptom was present but no exophthalmos. She was treated three times in three weeks, each exposure being ten minutes, with a medium soft tube. Fourteen days after the last exposure the enlargement of the gland had dispense of the gland appeared, also the systolic murmur, and there was an increase in weight of eight pounds. These improvements were still present seventeen months later, and the weight

had increased to fourteen pounds.

Case II.—Patient was a woman, forty-three years old, who had been complaining for two years of palpitation, and difficult urination. She was poorly nourished, with double exophthalmos, bilateral goitre, and nephroptosis and gastroptosis. Following an operation for nephroptosis the Basedow symptoms increased. There was also present tremor of the hands and a systolic cardiac murmur. treatments in five days were followed by so much improve-ment that she was discharged. When examined twelve months later, she was feeling well, with no Basedow symptoms, no exophthalmos, the goitre was smaller, and her weight had increased.

CASE III.—Patient was a girl, twenty-six years of age. CASE III.—Patient was a girl, twenty-six years of age.
During eight weeks she had noticed a swelling of the
neck, excitability, tremor of the hands, insomnia, and
sweating. She had slight exophthalmos, a systolic murmur, pulse rate 124, and the thyreoid was of the size of a
hen's egg and not compressible. Four treatments in three
weeks caused the symptoms to diminish. The goitre decreased two centimetres. After five months she was well
except for some enlargements of the thyreoid.

CASE IV.—Patient was a woman, forty-eight years of
age. She had been treated for Basedow's disease by

age. She had been treated for Basedow's disease by medicinal means for three years, with some improvement, but finally there was an increase in the symptoms—rapid loss of weight, great weakness, orthopnea (40), cyanosis, increased cardiac dullness to the left, and a loud systolic murmur at the apex heard also at the other valves. Pulse

was small and irregular. The liver was enlarged, cedema was present, there was a tremor of the hands, increased reflexes. The right lobe of the thyreoid was the size of a walnut and not compressible. Internal treatment caused the cardiac weakness to disappear, but the Basedow symptoms remained. Four treatments in five weeks caused these symptoms to disappear. Immediately after the first treatment she complained of vertigo and headache. The other treatments caused no symptoms. In the five weeks under Röntgen ray treatment she had gained ten pounds

CASE V.—Patient was a girl, eighteen years old, who had been generally nervous and had tremor of the hands and palpitation of the heart for six months. She was pale and emaciated. She had a goitre on the right side the were increased. There was no cardiac enlargement and the pulse was 92. She was given two treatments in two weeks. After the second week, the goitre had nearly disappeared, and after four weeks all the other symptoms

had disappeared

From these results Freund concludes that the exposure to the rays causes the disease of the thyreoid to disappear, and thereby the symptoms. The body weight then increases, and the other symptoms may disappear. The soft compressible goîtres are more easily influenced, and it appears that the more recent the development, the more rapid the disappear-

Rutinger (Deutsche medizinische Wochenschrift, 1907, No. 1) found that after each exposure there was a diminution in the excretion of nitrogen and an increase in the phosphates. Both his patients showed increase in weight, a diminution in the circumference of the neck, and an improvement in the nervous symptoms. He concludes from these investigations on the metabolism in these two patients under treatment that if, after a single exposure, the previously increased breaking down of albumin is replaced by retention of nitrogen the Röntgen ray treatment should be continued.

De La Cany (Mitteilungen des ärztlichen Vereins, Marburg, February 21, 1907) reported three cases. He does not agree with Rutinger that the retention of nitrates is directly due to Röntgen ray exposure, but rather that the cure of the disease is followed by this retention. In one of his patients galvanization of the sympathetic nerves previous to the Röntgen ray exposure was followed by

good results.

Wiederman (Gesellschaft für innere Medisin und Kinderheilkunde in Wien, January, 1906); reports three cases. In one, only an increase in weight was observed. In the other two there was an increase in weight and an improvement in all other symp-

Hirschl (Verein für Psychiatrie und Neurologie in Wien, February 13, 1906) reports two cases in which good results were obtained. There was an increase of about ten pounds in weight, a decrease in pulse rate, and a remarkable improvement in the

Schwarz (Verein für Psychiatrie und Neurologie in Wien, February 13, 1906) reports the case of a young girl of twenty-one years in which very good results were obtained: Pulse was reduced from 120 to 80, exophthalmos decreased to half, the dyspnæa disappeared, and the weight increased twenty-six pounds, but the goitre remained the same.

Holzknecht in discussing these reports believed that the Röntgen rays cause cell degeneration in the diseased parenchyma of the thyreoid and thereby cause a decrease in the pathological secretions.

Stegmann (Wiener klinische Wochenschrift, 1906, No. 3) reports three cases, in which excellent results were obtained. The goître and the other symptoms disappeared and the weight increased. He believes that the rays cause alteration in the cells of the gland which lead to qualitative and quantitative changes in the secretion.

Sklowdowski (Deutsche mediziniche Wochenschrift, 1906, Nos. 30 to 36).—A fifteen year old girl had been treated with antithyreoidin, under which treatment the nervous symptoms disappeared without affecting either the goitre, the exophthalmos, the tremor, or the pulse. Prompt improvement followed the exposure to the rays. There was an increase in weight of tweny-two pounds in two months. The improvement was permanent at least

a half year to the time of the report.

Beck (Berliner klinische Wochenschrift, 1905, No. 20) reported three cases in which Röntgen ray treatment followed operation. The first two had half the thyreoid removed, respectively eighteen and thirteen months. Their operations were followed by improvement, but not complete recovery. After a few exposures, the tachycardia and the nervous symptoms improved. These results led him to use the rays in a third case eight days after the operation. This third case was an especially bad one. In two days one five minute and one ten minute exposures were given. The pulse dropped from 180 to 120. The palpitation of the heart and the dyspnæa disappeared. Five treatments produced a dermatitis. One week later the pulse was 80, and the exophthalmos and all the Basedow symptoms had disappeared.

Beck (Journal belge de radiologie, 1908, No. 7) later reported on eight patients. All were cured except one, and this one interrupted the treatment too often. The first three had remained well three He considers the cases most favorable in which the gland is soft and in which the parenchyma is involved. He recommends the rays as a supplement to operations, when the thyreoid is large; when the symptoms are severe and forbid an immediate operation; and when the goître is small. (Postgraduate, twenty-fifth anniversary, 1908.)

Dohan (Verhandlungen der deutschen Röntgen Gesellschaft, July, 1907) reports eight cases. Two patients who had the typical symptoms have been well eight months and a year respectively, and free from all symptoms, excepting that one still has slight exophthalmos. One gained twenty-two pounds in eight months, and the other gained eighteen pounds in three months. In two other cases there was marked improvement. In four additional cases there has been practically no change even after several months' treatment, excepting that one patient gained in weight, and another had some reduction in the size of the goître. Dohan gives a dose sufficient to produce a mild dermatitis at each seance and then waits two weeks before repeating.

De Castello (Dritter Congress der deutschen Röntgen Gesellschaft) reports the case of a woman, sixty-eight years old, who had a goitre for fortyeight years, but in the last year it grew rapidly, and was the size of an apple and extended beneath the sternum to the third rib. One exposure by Kienböck, from three directions, aggregating over an hour in time, was given. In nine days the tumor was reduced to half the size, signs of toxæmia developed, and Gräffe's symptom appeared. goitre continued to decrease, but the Basedow symptoms did not improve. He concluded that the first

exposure should not be an excessive one. Fabers (Hospitals Tidende, August 21, 1907) reports eight cases of exophthalmic goitre with remarkable results in a few instances, even allowing for a spontaneous tendency to recovery in some cases, and the effects of suggestion in others. patient, a married woman of twenty-five, had presented the symptoms for four years, but they subsided under seven applications of the Röntgen rays for ten minutes in the course of twelve days. The same treatment was repeated about a month later. Four months afterward she wrote that she had never felt so well.

Summary.

There have been recorded in the literature at least fifty-one cases treated by the Röntgen rays. Of this number forty-two cases were followed by good results. In nine patients there was little or no improvement. In other words, good results were obtained in over seventy-five per cent. of cases, with no risk to the patient and no great inconvenience. This is surely in marked contrast to the results obtained by other methods.

The number of cases treated is still small, but surely sufficient to justify further trial, since there seems to be nothing lost and a chance for much gain

by the trial.

One author states distinctly that three of his patients received no other treatment. It is possible that others received no other treatment, but it is to be assumed that in most cases some internal treatment was used. Beck used the rays after surgery failed to produce satisfactory results, and recommends a combination of operation and Röntgen ray treatment. Since, however, results followed so promptly after all other methods had failed it seems folly to leave the best and least harmful method until last. It will be observed that the good results showed themselves in some instances within fortyeight hours, and almost without exception within a In most cases almost complete recovery was obtained in from three to six months. It would seem, therefore, that the trial of the Röntgen rays for a month, with from six to a dozen treatments, could do no harm, and is likely to be followed by good results. If some improvement is not shown in a month it should be discontinued for at least a month.

The treatment should be localized upon the goître, and may be carried to the point of producing a mild dermatitis, but not more. The first dose

should not be excessive.

The permanency of the results is still a question, yet all the patients in which good results had been obtained, had improved or remained well up to the time of the reports, which varied from a few months to three years.

The earliest and most noticeable improvement is the increase in weight. This is followed by improvement in all the symptoms. The two symptoms that remain longest are usually the enlargement of the thyreoid and the exophthalmos.

Conclusions.

1. Decided improvement may be expected in about seventy-five per cent. of cases.

2. This improvement consists of an increase in weight and strength, and gradual disappearance of the Basedow symptoms.

3. Some improvement should be noticed within a

month, and after six to a dozen treatments.

4. When this treatment is properly given there appears to be no danger, and I can see no objections to recommending this trial of a month in all

1321 SPRUCE STREET.

A CASE OF SQUAMOUS CELLED EPITHELIOMA,

Apparently Primary in the Thyreoid Gland. Metastatic Growths in the Lungs, Lymph Glands, and

By W. MILTON LEWIS, M. D., Baltimore, Md.

So few cases of squamous celled epithelioma of the thyreoid gland have been recorded that the report of an additional one, which was observed by the writer a few years since, appears at the present time of value.

Unfortunately, because of the incomplete autopsy, it is not possible to definitely say that the seat of primary growth was the thyreoid gland, but the great size of the tumor mass in the thyreoid gland, the extensive ulceration, and the absence of all symptoms pointing to a primary lesion elsewhere, make the diagnosis extremely probable.

Clinical history: Mrs. X, white, married, at. 64, consulted Dr. Charles E. Simon, of Baltimore, in the fall of 1896 for relief from cough, expectoration and general debility.

Family history: Mother, sister, and several brothers died

of tuberculosis

Previous history: Patient passed through the usual diseases of childhood. She was married about the age of twenty-five. Her husband thinks that she had a small goitre at the time of marriage, but she is of the opinion that the enlargement did not come on until after the birth of the first child, which took place one year after marriage. It then began to grow, and became quite prominent. It gave no trouble, however, excepting that due to shortness of breath. Her weight at the time of marriage was 108 pounds, but increased within two or three years to 152 pounds. At the age of thirty-two, she had intermittent fever. She had two children in addition to the one already wentioned the less one at the age of twenty nine. With mentioned, the last one at the age of twenty-nine. With the exception of an attack of dysentery in 1890, she was otherwise in good health until the fall or winter of 1895. The occurrence of a death in the house during this winter disturbed her a great deal.

Several months ago she began to have cough and expectoration, the cough being very distressing at night, and interfering markedly with sleep. The patient lost some flesh, and weighed about 125 pounds.

Present history: Patient first seen in October, 1896, and

Patient is of small stature, complexion sallow, expression anxious, and eyes slightly protruding. The general nutrition is fair. The left supraclavicular region is occupied by an irregular hard mass, which is continuous with the right lobe of the thyrcoid.

The pulse rate is 120 per minute. Cardiac dullness is within normal limits, and a very soft systollic murmur is audible at the base. Respirations are increased in frequency. The lungs are clear on percussion, both in front

and behind. At the right base behind, a few moist râles are audible. In front the respiratory murmur is distinctly enfeebled in the left infraclavicular region. Liver and spleen are within normal limits. Abdominal examination negative in general. The uterus is entirely prolapsed. The urine is free from albumin and tube casts, and contains no

Examination of sputum: The sputum was frothy and ood tinged. The total quantity in twenty-four hours was blood tinged. The total quantity in twenty-four hours was ten ounces. Upon careful examination no tubercle bacilli and no elastic tissue were seen. There were no cells pres-

ent suggesting carcinoma.

During the ensuing three or four weeks, the patient remained about the same. The mass in the left supraclavirular region became distinctly softer. The temperature varied between 98° and 101° F. The cough continued about the same, but the expectoration was a little less bloody, the saile, which the capeting and light red in color. Patient suffered especially from violent paroxysms of coughing, which were most distressing at night, and the weight remained about

On November 29th, the doctor was called at 7 a. m., and the following condition was noted: The patient had passed a wretched night, the color of the face was ashy, and there was a considerable degree of dyspnœa. The pulse was 140, weak, and very irregular. Free stimulation with whiskey, strychnine, and digitalis being resorted to, there ensued a very considerable improvement, the patient becoming quite

comfortable by evening.

On December 3d, the patient was transferred to the Johns Hopkins Hospital, where she remained until December 17th. On December 10th, she was seen by Dr. J. N. Mackenzie, and a small papilloma was removed from the anterior commissure of the 'arynx, with considerable relief from the violent paroxysms of coughing. The patient's general condition, however, continued to grow worse, and during the next ten days, the odor of the expectoration became very offensive. On December 17th, the patient returned to her home, and was manifestly much worse. Morphine had to be administered once or twice daily in order to relieve the distressing cough. The patient was, moreover, unable to take anything but liquid food, and this only in very small amounts.

amounts.

On December 10th, a fluctuating swelling was noted in the left supraclavicular region. Upon incision into this, a teacupful of bloody pus, very similar to that seen in cases of amebic liver abscess, was discharged. No ameeba were found in the pus, but a large number of cells, epithelial in appearance, were seen. These cells were probably correctly regarded as being referable to a carcinomatous growth.

December 21st: The patient had spent a miserable night, and at 5 a. m. a copious serous discharge was noted taking place from the wound. At the same time the hissing sounds of escaping air were heard during respiration.

On December 23d, after a fair night, the patient was still able to take a moderate amount of nourishment, but it was noted that some of the food escaped through the wound.

December 25th, at 9:30 a. m., the patient was manifestly dying. She was, however, still conscious at 4 p. m. At 4:30 p. m., tracheal râles were heard, the pulse was scarcely perceptible, and death occurred at 4:50 p. m.

The clinical diagnosis made at this time was carcinoma-

tous degeneration of the old goître.

Autopsy 8:30 p. m., December 25th, 1896. Section, four hours after death, length of body 160 cm. Rigor mortis fairly well marked, emaciation considerable, with a moderate grade of cachexia. Mucous membranes pale, pupils equal, eyes and mouth closed. Post mortem mottling of the dorsal surfaces of the neck, shoulders, back, buttocks and legs.

In the left supraclavicular region was seen a linear incision between 3.5 and 4 cm. in length, from which a sero-sanguinolent fluid exuded. Lying in front of the trachea, and corresponding in position to the thyreoid gland, was a swelling of considerable extent. Upon the left side, this mass appeared of cartilaginous hardness, and was rough and mass appeared of carriagnous naturess, and was rough and nodular. A finger passed through the incision already men-tioned was readily carried down behind the mass. The walls of the cavity were rough, crumbling readily upon pressure, and containing gritty or calcareous particles.

The right side was smooth in outline, uniformly enlarged, and precinted a degree of resistance suggesting dense fibrous tissue. None of the superficial lymph glands were enlarged, nor were there any moles or marks present. There was no œdema. No nodular masses or bony swellings were anywhere present, except as already noted.

The thorax was opened by an incision beginning at the upper border of the cricoid cartilage, and extending as far as the tip of the xiphoid cartilage. The tissues were bloodless and flabby, and the subcutaneous fat about two centimetres in thickness.

Dense fibrous adhesions bound the left lung firmly to the wall of the thorax. These were most marked in the lower portion. About 200 c.c. of bloody serum, closely resembling that exuding from the incision already mentioned, were found in the left thoracic cavity. There were a few slight adhesions present on the right side, and the serum con

tained in the right plural sac was normal in appearance and amount.

The lungs were mottled in black, or bluish black gray spots, crepitated under pressure, and floated upon water. In the apex of the left lung an area 1.25 by 5 cm. in extent was observed, which was of a leathery consistence, and of a grayish white mottled color. Upon section, this mass was smooth, opaque, and of a grayish white color, somewhat paler than upon the surface, and measured one line in thickness. A little reddish frothy serum could be pressed out from the lung substance beneath this mass.

Upon the anterior surface, 3.75 centimetres below the pex, a shallow, irregularly round depression was seen. This depression varied from one to four lines in depth, and its walls corresponded in general macroscopical appearances to the structure of the first described mass. Upon section, an area 5 by 2.5 by 1 cm. was revealed, which was dense, fibrous, and in some places cartilaginous to the touch, and which contained a cavity of very irregular shape, over the surface of which a smooth, glistening layer of tissue was spread, which closely resembled endothelium, but was

slightly more opaque.

Scattered throughout both lungs were small, dark areas,

Scattered throughout both lungs in diameter, each containwhich averaged about two lines in diameter, each containing in the centre a small, grayish white, globular mass, of about the size of a millet seed, and which was very hard, cutting with much difficulty. No nodules were to be found

on either the visceral or parietal pleura.

The heart was not enlarged, and occupied its normal position in the thoracic cavity. The pericardial sac contained about 15 c.c. of bloody serum. Covering almost the entire surface of the heart was an abundant fibrous ex-udate, which was dense, and which was principally composed of villous masses of fibrin, which were more or less elevated above the free surface, constituting the so called "hairy heart." It measured 16.25 by 15 by 8 cm. The wall of the right ventricle was thin, averaging about 1 cm. in thickness. The outer one third to one half was of a yellowish color, and projected beyond the level of the surrounding muscle. It was collected into clumps or lobules, and was of a greasy feel. In the apex of the right ventricle was a mass measuring 2 by 2.5 cm., which projected into the lumen of the ventricle, apparently corresponding to one of the musculopapillares. This mass was surmounted by a thrombus, which was undergoing organization. Upon section, this mass had the same general characteristics already described in connection with the deposits found in the lungs, i. e., the surface was smooth, more or less homogeneous, of a grayish white, mottled color, and quite dense and hard. It was, however, somewhat softer, and not quite so smooth, as the masses in the lungs, and very fine, gritty particles were scraped away from its cut surfaces, which had a somewhat milky appearance.

The wall of the left ventricle was of an average diameter of 2 cm., one quarter to one third of this space being made up of yellowish, lobulated, greasy masses, similar to those found in the right ventricle. The auriculoventricular valves were normal. Large yellowish white, opaque patches, varying from 0.35 to 2.5 cm. in diameter, were scattered over the inner wall of the larger blood vessels. These patches were particularly well marked around the origins of the innominate, the carotids, the subclavian, and the intercostals. They also extended into these vessels, as well as into

the coronary arteries

The mediastinal glands were considerably enlarged, and particularly so, one very large cluster situated at the base of the heart. In the latter mass two small cysts were noted, which were surrounded by a light colored border, which was irregular, dipping down into the surrounding tissue.

A small nodule about the size of a millet seed was found in the wall of the esophagus, just where it passed behind the arch of the aorta. Immediately above this point, 3.75 cm. above the origin of the left carotid, a small ragged opening in the wall of the esophagus, 2.5 by 0.85 cm. in size, was seen, which communicated with the abscess cavity

to be presently described.

Examination of the thyreoid gland showed a considerable enlargement of the whole organ, the two lobes, together with the isthmus, measuring 14.25 cm. transversely and about 3.75 cm. perpendicularly at the isthmus. The left lobe measured 10 by 10 by 2.625 cm. It was extensively necrotic, and communicated with the esophagus, the trachea, and with the artificial opening made in the supraclavicular region, in each case by means of several ragged openings. The walls of this abscess cavity were very ragged and friable, the tissues being easily scraped away by the finger. Extending in various directions across the cavity were trabeculæ, some of them of almost bony hardness, and very brittle, but which did not crumble under pressure. This abscess cavity extended deeply into the cellular itissues below the thyreoid, its deepest portions being 10 to 12 cm. below the external artificial opening.

One of these pockets extended deeply down behind the arch of the aorta, resting directly upon the wall of that vessel. Another area of ulceration passed down in front of the great vessels to the base of the heart, reaching about the same level. In front of the trachea, and about 1.25 cm. below the lower border of the thyreoid isthmus, just at the beginning of the pocket which passed in front of the aorta, were three ragged openings which communicated with the abscess cavity, and which varied from 0.625 to 1.875 cm. in length. These openings were subcutaneous, and were connected through the subcutaneous cellular tissues with the

supraclavicular incision.

Posteriorly, a communication existed between the trachea and the abscess cavity by means of several ragged openings, the largest of which was 0.625 by 1.875 cm. in size. These openings were situated about I cm. below the lower border of the cricoid cartilage. Above this point, the tracheal mucous membrane was smooth and pale, while below it was very dark red, this injection extending about 7.5 cm. downward

The trabeculæ were for the most part bony in appearance, although in parts of the mass calcareous deposits were found. At the base of the heart a mass of calcareous matter occupied the situation of a group of bronchial glands.

Masses similar in appearance to those found in the lungs were also found in the bronchial glands. The margin of the epiglottis was rough and excavated, the mucous mem brane being necrotic. The right thyreoid lobe was unusually enlarged, was hard and fibrous, and upon section presented the characteristics of thyreoid tissue, i. e., cystlike formations, containing colloid, and embedded in a network of fibrous tissue. The acini were greatly distended, and the nbrous tissue. The acm were greatly distended, and the fibrous partitions were very robust, causing a very considerable increase in the size of the gland, as already noted.

An incision through the diaphragm being made, and the

liver being carefully palpated, no nodular involvement became apparent. The gallbladder and ducts were free. tween the liver and the diaphragm were some slight adhesions, which were, however, easily separated. The stomach was apparently normal. A complete examination of the abdominal viscera was not, however, permitted. The

cranium was not opened

The larynx, thyreoid gland, trachea, lungs, and heart, to-gether with the large blood vessels, were removed entire and placed in a five per cent, formalin solution for future

Microscopical examination of the tissues:

Small bits of each lobe of the thyreoid gland, the lung, the heart, the esophagus, the epiglottis, the lymph glands, and the blood vessels were hardened, embedded in celloidin, and stained by the hæmatoxylin eosin method.

Sections prepared from the left lobe of the thyreoid showed the presence of a chronic fibrous hyperplasia. groups of normal acini being separated from each other by dense bands of fibrous tissue, in which but few nuclei were present. Other acini were compressed and their outlines lost, their places being occupied by groups of small cells, having densely staining nuclei

Among these cells were seen a few small bloodvessels. and a supporting structure of more delicate fibrous tissue

The compression of these acini appeared to be due to the increased development of fibrous tissue. Some of the blood vessels were seen surrounded by dense aggregations of lymphoid cells, outside of which were alveolar groupings of large polyhedral elements with vesicular nuclei, some of them undergoing mitotic changes.

In many places, however, this alveolar marking was not so distinct, the individual cells being separated from each other by a more or less well defined fibrous tissue. At other points, these cells were arranged in the form of strands, as it were, being made up of two, three, or more rows, and separated from each other by connective tissue

in which were seen a few small blood vessels.

With a higher power, the endothelial lining of these vessels was seen to be swollen, and in some places penetrated by lymphoid cells. The walls of the abscess were necrotic. by lymphoid ceils. Ine waits of the assess were necroit. Scattered through the cellular areas were numerous epithelial whorls, the cells of which were undergoing hyaline degeneration. The individual cells entering into the formation of these whorls and the "cell strands" varied greatly in size and appearance. Many of them were necrotic and indistinct. Others, while not suggesting a genuine necrosis, were nevertheless not well differentiated by the hæmatoxylin eosin method, but were colored a dark brown or black, as though the stain were precipitated into the cell protoplasm.

Still others were exquisitely stained, the chromatin and achromatin elements of the nucleus standing out most beautifully. In some areas mitotic changes were taking place, and one could observe indistinct cell division in all its phases, both typical and atypical. The multiplication of these cells had produced ingrowths closely corresponding to tumors of the epithelial type. The cells making up these ingrowths seemed to correspond to cells of squamous epithelium, and not to those of columnar or cylindrical type.

Forming a part of the wall of the abscess cavity, and numerous trabeculæ extending across this space, were several masses of bony hardness, which upon decalcification showed the histological structure of bone.

In various regions was seen a more diffuse lymphoid cell infiltration, which appeared to precede the complete development of the growth. On one side could be seen the normal thyreoid gland structure, while on the other hand were isolated groups of the characteristic cells, together with varying degrees of acinal obliteration resulting from invasion of the interalveolar sæpta by lymphoid and epithelioid cells, preliminary to the formation of fibrous tissue.

The right lobe presented simply the characteristics of

fibrous or fibrocystic goître of long standing. The acini were distended with colloid material, but there was no evidence of malignant disease in this portion of the gland, nor in the thyreoid isthmus. The fibrous sæpta were much increased in size, and very scantily supplied with cells. In the lungs and heart were, however, some very interesting

In the grayish white areas in the lungs, to which reference was made, were seen growths which closely corresponded in structure to those already described as occurring in the thyreoid gland. The tissues in which these growths occurred naturally exerted some influence upon this development. We hence saw in the lungs evidence of bronchitis and lobular pneumonia. The exudate within the bronchi consisted of polymorphonuclear leucocytes, desqua-mated epithelial cells, lymphoid cells, mucus, and broken down tissue

The nodular masses apparently had their origin in the walls of a blood vessel, spreading outward from that point. The normal alveolar structure of the lung was obliterated, its place being occupied by collections of irregularly shaped cells, of considerable size, with large vesicular nuclei, mostly oval, sometimes round, and with faintly staining

protoplasm.

The type of growth corresponded closely with that alcells around many of the blood vessels and in the walls of the bronchi. The cells of the new growth formed villa like projections, which penetrated and destroyed the sur-rounding pulmonary tissue. In the heart was found a most interesting condition. Around blood capillaries were seen collections of cells, similar in appearance to those already described, and which in many instances appeared to be developed directly in the muscle fibres, sometimes even suggesting a direct transformation of the muscle fibre into tumor cells.

In some places the capillaries were left, the muscle fibres having faded out. In others, the muscle fibre could be traced directly up to its abrupt termination in a tumor cell. Here, as in the lung, when the tumor cells were found around a blood vessel, the nuclei of the endothelial cells were swollen and leucocytes had escaped from the lumen of the vessel into the surrounding tissue.

Under the low power, the growth in the heart presented the appearance of a network of epithelial cells, enclosing islands of a loose connective tissue, containing here and there fragments of muscle, and groups of lymphoid cells. Occasionally single epithelium like cells were encountered,

which had two or more nuclei.

In some places the muscular tissue was necrotic, while in other regions the connective tissue framework which supported the fibres remained. The cardiac tissue was not displaced by, but was transformed into the new growth. Most interesting were sections carried through the thrombus. Here was seen an ordinary organizing thrombus, situated upon the ventricular wall of the right heart, which was being invaded by the elements of the new growth, and which contained many alveolar cell clusters.

The individual cells making up this portion of the tumor

The individual cells making up this portion of the tumor were smaller than those situated either in the thyreoid or in the wall of the heart, but the manner of growth appeared entirely the same. Metastases were found in the lymph glands of the bronchial and mediastinal systems. In these glands the growth consisted for the most part of irregular groups of large cells, whose protoplasm was nongranular

and took the eosin stain.

Many of the cells had more than one nucleus, and were most well distinguished. In others, the nucleus looked like a mass of very darkly staining pigment. Occasionally very large elements were seen, in which the nuclei were filled with very large granules. The stroma between the groups of cells was plentifully supplied with capillaries and fibrous tissue elements in all stages of development. Numerous cells, with long, rod shaped, faintly staining nuclei, were seen, held together by a homogeneous ground substance. Mingled with these were cells containing yellowish brown pigment. This pigment also occurred free as varying sized collections of very fine granules. Around the new growth was a fibrous capsule, and around certain lymph channels could be traced groups of large cells with vesicular nuclei, which closely resembled those of squamous epithelium. The growth occurred sometimes as strands or columns, and sometimes presented the appearance of dense alveolar structure. When the alveolar structure was pronounced, the stroma was better developed, and here the resemblance of the tumor growth to squamous epithelium was very marked. The deeper layers were columnar in type, while as the middle of the alveolus was reached the cells became more or less polyhedral in outline.

These irregular polyhedral cells were nongranular, or at least but faintly granular, containing large oval vesicular nuclei, many of them exhibiting mitotic figures. The extent of involvement varied, in some cases the entire gland being included, and in others a part remaining normal. In some of the glands extensive necrosis had taken place, the changes being due for the most part to karyorrhexis. Scattered through the entire necrotic area were seen granules of

brownish pigment.

Sections of the œsophagus at various levels showed no involvement of the mucous membrane. In many situations the growth approached very closely to the lumen of the tube, and in one place, to which reference has already been made, there were several ragged openings. The borders of these openings were necrotic, but there was no evidence of carcinomatous involvement. In the blood vessels, as the zorta, carcitids, innominate, and the coronary arteries, the yellowish patches before described were due to the development of fatty atheroma. The walls of the vessels were largely composed of dense fibrous tissue.

No report was secured of the growth removed from the larynx, except that it was a papilloma. The nodule in the wall of the escophagus was an enlarged lymph gland. There were probably metastases in other organs, but their exam-

ination, as already intimated, was not allowed.

1226 Liebek Avenue

THE DIAGNOSTIC VALUE OF PERVERSE SECRETION OF HYDROCHLORIC ACID BY THE MUCOUS MEMBRANE OF THE STOMACH.

By Graham Chambers, B. A., M. B., Toronto, Canada,

Physician, Toronto General Hospital; Associate Professor of Clinical Medicine, University of Toronto.

In discussing the diagnostic value of perverse secretion of hydrochloric acid by the gastric mucosa it is well, I think, first to cite certain physiological facts bearing on the subject:

- (1) Pawlow and his pupils demonstrated that the vagus is the secretory nerve of the stomach, and that it contains stimulating and probably inhibitory fibres
- (2) Gastric juice, the secretion of the various glands of the stomach, is a clear liquid containing in addition to a small amount of mucus and some mineral constituents, hydrochloric acid and three ferments, namely pepsin, rennin, and gastric lipase.
- (3) Pawlow showed that there are two phases in gastric secretion. During the first phase psychic impressions such as the sight and odor of food, desire to eat (appetite) and mastication are the stimuli; and during the second some form of chemical stimulus is the excitant. He was also able to demonstrate that mechanical irritation alone is unable to produce a flow of gastric juice.
- (4) Edkins extracted from the pyloric mucous membrane of a dog a substance, gastric hormon, which when injected into the blood of an animal produces a free secretion of gastric juice. This, he believes, is the stimulus of the second phase of secretion in the stomach.

This hormon would naturally be produced as long as substances are present to act upon the pyloric mucous membrane.

- (5) The acidity of the native juice of a dog, obtained from a gastric fistula, the animal being "sham fed," was found by Schoumow-Simanovski to be 0.46 to 0.58 per cent.
- (6) In the case of a girl with fistulæ of the œsophagus and stomach, subjected to "sham feeding," Bickel found the acidity of the native juice to be relatively constant, varying from 0.35 to 0.55 hydrochloric acid. Bickel is of the opinion that the variation of acidity depends principally upon the degree of neutralization of the juice by gastric mucus. Similar results have been obtained by other investigators.
- (7) The principal function of the stomach is to convert the food into a gruelly mass fit for intestinal digestion. This is brought about by gastric ferments, especially by pepsin in presence of hydrochloric acid, which dissolves gelatin forming substances, elastic tissue, and all true proteins.

(8) The evacuation of the stomach is due to tonic contraction of the fundus and peristalsis of the pyloric portion. Cannon demonstrated this by radioscopical examination.

(9) The chyme is not propelled into the duodenum continuously but in jets, the pylorus opening and closing alternately.

+10) Serdjukow demonstrated that the pylorus

remains closed as long as the duodenal contents are

These are normal physiological phenomena and should always be kept in mind when one is studying perversion of gastric functions. It will be observed that the native juice, free from food, obtained from a gastric fistula during "sham feeding" has an acid content more than twice that of gastric contents, after a test breakfast. If one gives a meal 35 grammes of white bread and 400 c.c. of water or weak tea without sugar or milk, and after an hour removes by siphonage the gastric contents, the normal acidity calculated as hydrochloric acid varies from 0.14 to 0.22 or 40 to 60 (expressed in 1/10 solution sodium hydroxide). However this is not the acidity of the gastric secretion but of the native juice, modified by the evacuation of acid chyme into the duodenum and by partial neutralization by saliva, food, mucus, and transudate. Thus there are so many factors which take part in the genesis of the acid content of gastric contents that it is very difficult in some cases to determine the kind and degree of perversion of gastric secretion by chemical analysis. I can readily imagine cases of diminished secretion of gastric juice as a whole (subsecretion) diagnosticated, by our present methods of examination, as hypochlorhydria; and similarly hyperchlorhydria may be mistaken for oversecretion. This view is, I think, supported by my observation in cases of chronic gastritis, carcinoma of the stomach, and achylia gastrica, in which the absence of marked motor insufficiency, diminished percentage of hydrochloric acid is usually associated with greater consistency of the gastric contents; and similarly hyperchlorhydria with diminished con-This character of gastric contents is usually evident from visual examination and from the viscosity as determined by means of a stirring rod. I have also confirmed it by determining the specific gravities of the gastric contents. As a rule diminished percentage of hydrochloric acid is associated with an abnormally high and increased percentage, in the absence of much mucus, with an abnormally low specific gravity.

In this connection one should remember that the maximum percentage of hydrochloric acid in native juice is 0.58 or about 160 (expressed in c.c. 3/10 solution sodium hydroxide) which according to my observations is greater than the total acidity (per cent.) of the gastric content in the most severe form of hyperchlorhydria. The writer after analyzing a large number of gastric contents-probably one thousand—has never observed a total acidity above 140. This suggests that increased percentage of hydrochloric acid in gastric secretion may be a rare occurrence. In the past we have paid too much attention to percentage and too little to mass of hydrochloric acid in gastric contents. I may add that I know of no evidence, physiological or pathological, which proves beyond doubt that the percentage of hydrochloric acidity in the secretion of

the stomach is subject to marked variation. In gastric analysis we do indeed find great variation in percentage of hydrochloric acid in the contents of stomach after a meal; but this may be explained by variation of gastric secretion as a whole or by variation in degree of neutralization by saliva, mucus, food, and transudate, and also possibly in some cases by bile and pancreatic juice.

The motor and secretory functions are so interdependent that in interpreting the results of chemical analyses it is frequently very difficult to determine which perversion of function is the more important morbid factor.

According to the teaching of physiologists—confirmed, I believe, by clinical experience-motor insufficiency due to spasm or stenosis of the pylorus, gastroptosis, or myasthenia gastrica should modify the acidity of the gastric contents which in the absence of carcinoma, pernicious anæmia, and other markedly debilitating diseases is usually an increase in the percentage of hydrochloric acid.

On the other hand over secretion of hyperchlorhydria by producing spasm of the pylorus might modify the gastric motility. The observation of Edkins has an important bearing on this relationship of motility to secretion. He has shown that the chemical stimulus of gastric secretion is a hormon formed in the pyloric mucous membrane, during gastric digestion. One should expect therefore the chemical phase of gastric secretion to continue as long as there are substances in the stomach to act upon the pyloric mucous membrane. This is a most important consideration in studying the pathogenesis of gastric affections. Perversion of motor function is a very common disturbance in diseases of the stomach; and is probably more active than perverse secretion in causing subjective symptoms. Patients whose gastric contents show a high percentage of acidity frequently suffer more from stagnation of food and hyperæsthesia of the gastric mucosa than from excess of acid. Hyperæsthesia especially is a frequent cause of subjective symptoms, particularly in patients suffering from some forms of neurasthenia. A patient with normal percentage of hydrochloric acid in gastric contents may have subjective symptoms very similar to those usually observed in cases of the so called hyperchlorhydria. Thus in two cases recently under my care the analyses of gastric contents were practically normal but still the patients suffered from heartburn, pain after eating, and other complaints usually observed in the symptom complex of the so called hyperchlorhydria. The pain was relieved by the ingestion of food or by the exhibition of baking soda. These patients suffered, I believe, from neurasthenia with hyperæsthenia of the gastric mucosa.

In the treatment of diseases of the stomach these facts are very important. In the past, particularly in cases of gastric neuroses, too much contention has been given to percentage of hydrochloric acid in the gastric contents and too little to the motor and sensory functions, and psychic state of the

I shall now briefly state some observations and considerations on some diseases of the stomach usually characterized by perverse secretion of gas-

In 1842 Golding Bird showed the absence of free hydrochloric acid in the gastric contents in a case of carcinoma of the stomach. However, very little attention was given to this observation until Van der Velden in 1870 made some observations in a series of similar cases. Since then this has been looked upon as one of the most useful signs in the

distinctive diagnosis of gastric diseases.

There are, however, many exceptions to the rule, particularly in the early stages of the disease. According to my observations free hydrochloric acid is present in about ten per cent. of the cases at first examination. In the advanced stages of the disease the exceptions become fewer probably less than five per cent.

With regard to the sign of cancer I feel that many physicians have a wrong conception of its They speak of the absence of free hydrochloric acid as a sign of perversion of gastric secretion quite distinct from diminished secretion of gastric juice or of hydrochloric acid. One should remember that free hydrochloric acid only appears in the contents of the stomach after the saliva, food, mucus, and transudate are neutralized or chemically satisfied. If the gastric secretion do not contain sufficient acid to satisfy all these affinities then free hydrochloric is absent; but combined hydrochloric acid, i. e., hydrochloric acid loosely combined with protein, may be present. After a time the quantity of this acidity diminishes until in advanced cases there may be neither free nor combined hydrochloric acid in the contents of the stomach. we take this idea of the perversion of secretion then the condition of the stomach before the development of the carcinoma must be taken into consideration; and we can also give an explanation of the exceptions, i. e., cases in which free hydrochloric acid is present in gastric contents.

According to my observations all the cases of cancer of the stomach, in which free hydrochloric acid was present in advanced stages of the disease, gave a history of having suffered from gastric ulcer or acid gastritis, affections usually characterized by excess of free hydrochloric acid in gastric contents, and frequently by a large excess. I am aware that cases have been recorded in which free hydrochloric acid was present in advanced stages with no previous history of gastric diseases. It is possible that in some of these cases an acid catarrh might have been present without producing appreciable dis-

tress.

The absence of free hydrochloric acid in gastric contents or better diminished secretion of gastric juice or of hydrochloric acid is, I believe, a valuable sign in the diagnosis of gastric cancer. Alone it is of very little value, as it is also a sign of acute gastritis, chronic catarrh of the stomach, pernicious anæmia and other affections. Associated with other signs such as rapid loss of weight, vomiting, presence of Oppler-Boas bacillus, much lactic acid in gastric contents, coffee ground vomitus, etc., it is very valuable, particularly in the absence of palpable tumor. Without it, it would be frequently impossible to make a diagnosis.

Acid Gastritis

This is a chronic disease characterized by excess of mucus and of hydrochloric acid in gastric contents. The total acidity is high (70 to 120), of which free hydrochloric acid is 20 to 60.

According to my observations this gastric affection is common among alcoholics. In fact over 80 per cent. of the cases of chronic gastritis among

persons who use alcohol in excess have been characterized by excess of hydrochloric acid in gastric contents.

Another observation worth recording is the not rare association of this affection with gastric ulcer and carcinoma. My experience teaches me that acid gastritis predisposes to both ulcer and carcinoma. The latter is more apt to develop in persons who have a hereditary predisposition to malignant disease.

When carcinoma complicates acid gastritis or gastric ulcer free hydrochloric acid may be present in advanced stages of the disease. This is particularly true of cancer engrafted on a pyloric ulcer, in which I have observed in five cases free hydrochloric in gastric contents in very advanced stages.

Achylia Gastrica.

This is a disease characterized by absence of free as well as of combined hydrochloric acid in gastric contents. It may be primary neurosis or secondary to organic disease of the gastric mucosa.

The symptomatology, of course, varies with the pathology of the morbid condition. A symptom of common occurrence is chronic diarrhœa. One should, therefore, in patients suffering from chronic diarrhœa, always consider achylia as a possible cause.

In my practice there have been at least three cases of achylia gastrica of the primary type. In one patient, a physician suffering from Graves's disease, there was a history of chronic diarrhœa of fifteen years' duration. In another, a Swedish woman who had lost a husband and four children with tuberculosis, there was a history of diarrhœa of four years' duration.

In both of these cases the exhibition of dilute hydrochloric acid checked the diarrhœa. This suggests a use of hydrochloric acid in the diagnosis of achylia. Whether achylia is present in all cases of diarrhœa controlled or cured by the administration of a mineral acid I am not prepared to state; but I do know that hydrochloric acid is a most useful agent in the treatment of diarrhœa in cases of pernicious anæmia and of severe infections, diseases in which achylia may be present. How it acts it is difficult to explain. Possibly by starting peptic digestion it leads to the formation of the gastric hormon which stimulates gastric secretion. With gastric juice in the stomach the food is protected against putrefaction and prepared for intestinal digestion, and the normal mechanism of the pylorus is restored.

HYPEREMESIS DURING THE GRAVID STATE IN TWO SUCCESSIVE PREGNANCIES

By H. Grad, M. D., New York,

Assistant Surgeon of the Woman's Hospital.

In reporting this case of persistent vomiting in the early months of pregnancy in two successive gestations, only a clinical picture will be drawn, as no chemical and microscopical studies of the urine could be carried out, and only one blood examination was at hand. In both attacks of hyperemesis the clinical picture of the case was so alarming that radical measures were most urgently called for.

There was one feature in the case that was of interest in so far that a definite pelvic lesion existed. The patient was suffering with a retroverted gravid uterus, and in the absence of marked urinary changes the question arose whether relief could be given by replacing the gravid organ. Accordingly the uterus was replaced and held in position by pessary and packing, but without giving the slightest relief. In fact, during this procrastination the condition grew worse and a further delay might have

proved fatal. In the light of our present knowledge of hyperemesis, only the mildest cases of vomiting of pregnancy can be considered as "physiological" due to reflex causes, and it is a question if even these cases should be so considered. The literature abundantly shows that hyperemesis is a symptom complex of grave pathological process in the liver and kidneys, and that there is a close relation between this condition and eclampsia, as well as acute yellow atrophy of the liver. It has been demonstrated by careful investigators that the underlying condition in these diseases during the gravid state, is one of toxæmia; hence the term "toxæmia of pregnancy." condition of toxæmia of any kind is a most complicated one, very little understood, and the toxæmia of pregnancy is no exception. Out of the complex nature of the toxæmia of pregnancy this much has been learned, that there is a marked disturbance with the nitrogenous metabolism; the liver failing to oxidize the proteid derivatives into urea. The principal proteid derivatives are the amido acids and ammonia circulated freely in the blood. Ewing (1) says "The exact nature of the disturbance of introgenous metabolism which is responsible for the clinical manifestation of the toxæmia of pregnancy, is a failure of oxidizing capacity on the part of the liver. For this reason the proteid derivatives-principally amido acids and ammoniawhich are normally combined by the liver into urea, are no longer combined but circulate free in the blood in poisonous form, and are to some extent excreted by the kidneys." Ewing further says: "Besides ammonia and amido acids, other proteid derivatives-as those containing sulphur-fail to be oxidized and these doubtless contribute to the toxæmia.

In the toxemia of pregnancy, the urinary findings are of such a nature as to give us valuable information as to the severity of the intoxication. and hence the prognosis of the case. In these cases the urine contains acetone, diacetic acid, beta oxibutric acid, ammonia, uric acid, leucin tyrosin, indican; sometimes bile pigment, and other unoxidized proteid radicles, and instead of the sulphate salts the unoxidized sulphur compounds are found. Albumin and casts may be present in the urine, but even in the severe and fatal cases, both of these may be absent. Therefore, an ordinary urinary examination, such as can be carried out at the office of a physician, is of little or no value in cases of toxæmia of pregnancy. Only a complete urinary examination, carried out in a well equipped laboratory by a competent chemist and microscopist, can give us the desired information as to the degree of the disturbance of the introgenous metabolism in each individual case.

The complicated chemicophysiological questions involved in the toxemia of pregnancy have been studied from various points. Is the toxemia due to a chemical substance circulating in the blood, and if so, is it derived from defective metabolic changes in the organism, or does it reach the mother from the fœtus or placenta, are at present unanswerable questions.

The urine has been studied with greatest care in the toxæmia of pregnancy and it has been found that there is a disturbance in the normal ratio that exists between the nitrogen derived from urea, the nitrogen of ammonia, and the nitrogen of undetermined sources. Pregnancy has the effect of causing a disturbance in metabolism, resulting in lowering the excretion of urea, increasing the ammonia, increasing also the amino acids and those substances from which are derived the so called "undetermined nitrogen." As we cannot express in definite terms what really constitutes a normal nitrogen ratio in every case, it is also impossible to express numerically what constitutes an abnormal nitrogen ratio.

In a recent paper Dr. Craigins (2) says: "In order to intrepret the abnormal it is necessary to understand the normal nitrogen output"; and for this reason the writer placed in bed for nine days at the Sloan Maternity Hospital two normal pregnant women in their last month of pregnancy. Their diet was solely milk and water—the same diet which our toxæmic patients would be likely to have, and the nitrogen ratios in the twenty-four hour specimens of these women were determined by a professional chemist for each of the nine days, with the following results.

The average for the two patients for the nine days:

Urea nitrogen 83.26 per cent. of total nitrogen Ammonia nitrogen 5.16 per cent. of total nitrogen.

Amido acid and undetermined nitrogen. 6.43 per cent. of total nitrogen.

This may be taken as a normal nitrogen ratio in a gravid woman.

It has also been found that urinary findings and clinical evidences do not always harmonize. A patient may have a low urea nitrogen, high undetermined nitrogen, and present few or no symptoms of toxæmia. In her case the metabolism is disturbed, but she remains free from symptoms, while her sister with the same nitrogen ratio findings will suffer with persistent vomiting, headache, and undermined mental and physical vigor. In some cases the undetermined nitrogen ratio will be a better index of the severity of the toxæmia, while in other cases the high ammonia nitrogen ratio will be a better index.

Stone, the pioneer student of this subject, has divided these cases of hyperemesis gravidarum into three classes: 1, The fulminant; 2, the acute; and 3, the chronic type. The fulminant type proves rapidly fatal, with symptoms of acute yellow atrophy, without jaundice. The acute type develops jaundice, with high pulse, great prostration, nervous disturbance, while the chronic type may run into the preeclamptic stage. Ewing (3) says: "When toxemia develops in the early months of pregnancy, vomiting is usually prominent, low urea and high ammonia nitrogen is the rule, and the fatal cases take the form resembling acute yellow atrophy. When it develops in the latter months, vomit-

ing is less common, circulatory and cerebral symptoms are prominent, low urea and high undetermined nitrogen are usually found, with albuminia; and the fatal cases end in eclampsia." Ewing further says: "Considering the metabolic changes as indicated in the urinary nitrogen, there appears to be no distinct difference between eclampsia and preeclamptic toxemia and some cases of persistent vomiting."

While nephritis is more frequently present in the precelamptic stage of toxemia, and always present in eclampsia, it occurs also in cases of hyperemesis. In cases of persistent vomiting in the early months of pregnancy, the same patient may suffer with albuminuria in the latter months of her gestation. This may show apparently that the toxemia finally resulted in kidney changes, as is shown by signs of nephritis. Clinicians have observed cases with disturbed nitrogen ratio plus symptoms of toxemia, where several weeks later nephritis developed with a disappearance of the abnormal nitrogen ratio. It has also been observed that under the latter condition the prognosis of the cases is better than when a nephritis and a disturbed nitrogen ratio coexist.

The theory that the toxæmia of pregnancy is of the nature of an acid intoxication has been found lacking in so far as definite chemical confirmation goes. According to this view the toxemia results from abnormal acids circulating in the blood, these abnormal acids arising during the course of disturbed metabolism in the organism. The theory, however, fails to show why these acids develop. The suboxidation view explains the toxemia of pregnancy a little more favorably. According to this theory, toxic substances form and circulate in the blood because of the proteid bodies not becoming properly oxidized into urea and ammonia, and evidence of this suboxidation is abundantly found in the urine. A further clinical research into the question of oxidation has resulted in learning that it is not so much a question of true oxidation as of failure on the part of the metabolic processes to remove the so called amino group during the conversion of proteids into urea and ammonia. This particular failure of metabolism has been termed by Ewing "deficient desamidation." He further says, regarding the toxemia of pregnancy: "The conception of the disease as a disorder of metabolism removes much of the point in the long standing discussion whether the process is an affection primarily of the liver or of the kidneys and to what extent an hepatic insufficiency or intestinal intoxication may be The present theory of a deficient desamidation, itself of complex origin, places all of these factors in a subordinate position to the altered chemical processes in metabolism. Changes in structure and functions of the liver arise early in the disease, since the organ is chiefly, though not alone, concerned in nitrogenous metabolism. Once altered in structure by granular and fatty degeneration and crippled in function, there is good reason to believe that the liver contributes prominently in a vicious circle of influences which maintain the disorder. In this condition it often fails to detoxicate products of intestinal decomposition. At a later stage the kidneys are progressively involved by a mechanism which is little understood, and a prominent affection of this organ seems a necessary condition in eclamptic convulsions. In the latter months of gestation toxic products from the fœtus and placenta, and from the maternal tissues at all stages doubtless contribute to the complex picture of the disease, but all of these owe their existance and operation to the original disturbance of metabolism in the mother."

Not alone the abnormal urinary findings but definite pathological lesions in the liver, are the bases for establishing the toxemia of pregnancy as a definite disease. Eclampsia, acute yellow atrophy, and pernicious vomiting all may show pathological changes in the liver. Ewing thus describes (4) the liver changes in a case of eclampsia: "The liver in the gross is usually normal in size, reduced in consistency, while surface and section present many minute hæmorrhagical foci. Microscopically, there is a uniforn, and intense granular hydropic and fatty degeneration of the liver cells. which results in nearly complete disorganization of the protoplasm, and therefore in abolition of function of these cells there are also numerous focal necroses. There are finally many is ninute hæmorrhages, usually but not always, in renation to the necrotic foci. The lesion occurs practica lly without exception in all typical cases of acute fat; al eclampsia at term, and in at least ninety-five pent cent. of all cases of any variety of eclampsia, it is a pathognomonic of this type of the disease.

In the cases of acute yellow atrophy, the liver is diminished in size, and the microscope shows in the hepatic lobules a complete fatty degeneration continuous the interment wo thirds, an area of necroses and disprated cells outside of this, while the periphert of the lobules shows cells undergoing granular describes a case of acute yellow atrophy two month is after an abortion and calls the case "postgestational acute yellow atrophy." He says: "Liver weighed one pound ten ounces, was very soft, uniformly deep red, lobules obliterated." Microscopically, there are the changes of a late stage of acute yellow atrophy. Only a few islands of fatty liver cells remain. Nearly the entire organ is reduced to a disintegrated mass of microbical liver cells mixed with blood and bile.

That there are cases of toxemia without marked hepatic changes has been shown, but these findings do not necessarily argue that the toxemia does not depend on disturbance with liver function. The formation of urea is a liver function, and if the organ fails to functionate, a disturbance in the metabolism must occur. Disturbed function, however, does not necessarily mean anatomical changes. The histological changes in the liver cells may be very minimal, while the oxidizing capacity of the organ may be greatly at fault. As Ewing remarks: "The anatomical lesions certainly follow and do not precede the disturbance of function and there may very well be several steps between the loss of oxidizing capacity and the hydrolysis of fatty degeneration, and necrosis of the liver cells."

It is because of the inconstancy of the histological changes in the liver in some cases of toxæmia of pregnancy, that Herz, in 1868, elaborated the

theory of "functional paralysis of the liver." According to this theory the liver fails to oxidize the products of digestion into urea because the hepatic cells are functionally paralyzed. This paralysis is not easily explainable. Herz asserts that such a hepatic paralysis can be brought about experimentally by tying the ureters. It has also been stated that hepatic congestion is a frequent accompaniment of suppressed menses, irrespective of whether this suppression of menstruation is due to amenorrhœa, castration, menopause, or pregnancy. As a result of this circulatory disturbance hepatic enzymes fail to be produced, but no structural changes in the liver cells need, necessarily, occur. Under such a condition the oxidizing capacity of the liver will be at its lowest point, and this hepatic incapacity may continue for some time before histological changes occur in the lobules.

The following is the history of the case given to me by the attending physician, who saw the patient for the first time on October 25, 1906.

Mrs. B., age twenty-six, married six weeks, gave the following history: Her health had always been good, never suffered with stomach trouble or constipation. She began to menstruate at fourteen, and always normal. She flowed ro menstruate at fourteen, and always normal. She nowever your weeks with little or no pain. For the past three weeks she had been feeling very badly on account of the worstant nausea and vomiting. At first the vomiting occurred in the morning and once or twice during the day, but now the vomiting had become almost continuous and the property of the party retaining the party of t it was impossible for her to retain any nourishment whatsoever. She had to take to her bed, slept very little, bowels were constipated, and she complained bitterly of nausea and pain in the abdomen, especially the epigastric region. Temperature 98.6° F.; pulse 110. Vomitus green in color. The treatment at this time consisted of bismuth subnitrate, gr. x; cerium oxalate, gr. x; morphine sulphate, gr. ½, every four hours.

October 26, 1906. Vomiting stopped for short intervals, sometimes for a few hours at a time, but developed a burning sensation in the stomach. Bowels had not moved by enemata. She complained of acid eructations and burning in the stomach. Colonic irrigation was now resorted to

and rectal feedings given

She was not seen until November 16, 1907, when the attending physician was told that the condition of the patient had continued about the same; that she had remained in bed since October 26th; that all and every kind of food was vomited; that she did not sleep; that the pain

and burning in the stomach had continued

Bimanual examination showed the cervix long, uterus Bimanual examination showed the cervix long, uterus retroverted and gravid about two months. Iodine applications and tampons were now applied daily for three days without effect. Saline rectal injection, nutrient enemata were given, with iced champagne by mouth. Pulse 130; temperature 98.6° F. She had had no headache, but was externally restless. She rolled around the bed, turned from side to back and from back to side, scarcely remaintening and the position for more than a few minutes. She ing in any one position for more than a few minutes. presented the picture of abject distress and agony. She threw her hands about in a most restless fashion and begged bitterly for relief. While her actions simulated those of an hysterical patient, her face spoke eloquently of suffering and distress. Tongue was dry; examination of heart and lungs was negative. Vomitus green in color.

The whole abdomen was extremely tender to the touch and exceedingly hyperæsthetic. The slightest touch, especially in the epigastric region, caused most distressing retching. She moaned and groaned continuously. Her retching. She moaned and groaned continuously. Her condition had gradually become worse; she was delirious at times. Morphine in full doses gave no relief. She looked haggard, complained of pain in the abdomen, was very weak and restless, and prayed for death. Urine showed high specific gravity, was scanty in quantity, no albumin or casts. After consultation, uterus was replaced

and held in position with packing.

November 24th, patient was in very bad and dangerous condition. Pulse 140, weak, and temperature 99.6° F. She

was etherized and curetted. While recovering from the anæsthetic she vomited twice and her stomach symptoms

immediately began to improve.

November 25th. Pulse 150, weak, nutrient enemata con thread. On the third day following the evacuation of the uterus the patient began to take nourishment by mouth. She gradually regained strength and was out of bed in ten She soon grew stout, and gained twenty pounds over her average weight. The following month, examination showed uterus retroverted. Nothing was heard of her until March 27, 1907, when she said that she last menstruated on January 30, 1907, but did not have sexual relation until March 5, 1907. One week ago, or fifteen days after coitus, the begun to have proving sorting. she began to have morning vomiting. Since then the nau-sea and vomiting gradually increased and patient was unable to retain any food; even ice water was rejected. She was restless, unable to sleep, and complained of thirst and epigastric pain. Pulse 90; temperature 98.6° F; tongue clean. Heart and lungs normal. Great abdominal tenderness. Could not bear the weight of the bedclothes. Uterus enlarged and retroverted. Treatment consisted of cerium oxalate, cocaine, bismuth. No food by mouth, colon irrigation, nutrient enemata, etc.

March 28th. Vomiting was almost continuous. Patient

complained bitterly of epigastric pain and pain in the lower part of abdomen. She had to be restrained and watched constantly. Pulse 90; temperature 90° F. Under anaethesia uterus replaced and held there by tampons. Treatment

continued.

March 29, 1907. Patient's condition was much worse, similar to that in her first pregnancy. She vomited and retched continuously, and was delirious. Urine showed 1,030 specific gravity. No albumin, no sugar, no casts; urea 14 grains to the ounce. Blood showed over 4,000,000 red blood corpuscles; 11,000 whites; 85 per cent. hæmoglobin. March 30th. Patient was amesthetized, and uterus was emptied. Very profuse bleeding; pulse 130; uterus packed. Patient soon rallied. No vomiting after anæsthetic. Two days later food by mouth.

days later food by mouth.

April 7, 1907.. Patient out of bed and felt well, able to April 7, 1907.. Patient out of bed and felt well, able to take solid food. Urea secretion normal. When questioned she said she had no recollection of events three days prior to operation, and one day following.

THE NEED AND VALUE OF HEALTH INSPEC-TION WORK.*

BY LYMAN ASA JONES, M. D., North Adams, Mass., State Inspector of Health, District No. 15.

That the need for health inspection work should

require presentation and explanation to a body of every day citizens is easily understood. The average citizen thinks but little and knows less about matters pertaining to health. The subject seldom touches him individually except when preventable sickness has taken hold on him or some member of his family. And even then many of the more ignorant regard their case as something sent them by Providence, like the Frenchman whose house I was one day quarantining for diphtheria. After a somewhat lengthy disquisition upon the danger of infecting others and the precautions which should be taken, which I flattered myself I had made especially plain, simple, and convincing, the father of

^{*}Read at the annual meeting of the Massachusetts Medical Society, Boston, June 9, 1008.

the patient turned to me and said, "But, you know, I think the Lord He send these sickness, and it is not right to do anything to interfere with His will."

The sequel in this instance, owing to the lack of a contagious disease hospital, and the failure to realize that nothing short of a police guard would enforce quarantine, and owing to an entire change of the health board at this juncture, was that in related families near by a number of other cases occurred, two of which were fatal.

In another instance, when the mother of a little fellow who had diphtheria was remonstrated with for permitting the child to run about the house, and to cough and spit promiscuously, she replied, "He no sick, that no harm." That the remonstrance was ineffectual is shown by the fact that other cases occurred in the family, and that one or two of the

family died.

That this subject of health inspection and its need should require presentation to health officials not infrequently can also be readily understood in calling to mind the manner in which such bodies are formed and the personnel of which they are composed.

In cities, unless the charter provides otherwise, the mayor appoints annually a member of the board of health, one of whom must be a physician, to serve three years. As a matter of fact, in many cities the whole board is appointed annually. In towns the board of health may be elected, one member each year, to serve three years. In case no board is elected, the selectmen serve as such a board. If the population of the town is over 5,000, at least one member of the board, if there be such, must be a physician.

In consequence of this arrangement the larger places are apt to be better off than the smaller places. In the latter the selectmen frequently act as boards of health. The selectmen are largely representatives of one or another political party or faction, and they have no more knowledge of health matters than the ordinary citizen. Such medical advice as they may have occasion to seek from time to time, will not infrequently come from some one whose influence they desire to secure, or is made the occasion of returning some political favor, regardless of the qualification of the adviser to give sound and intelligent

They may refrain from insisting upon proper health measures or requirements for fear of estranging political supporters. In larger places this difficulty often arises from an unwillingness to proceed against prominent or influential citizens or corpora-

Narrow minded boards, through ignorance or failure to realize the necessity for health work, refrain from spending money through a desire to keep the expenditures under, and imagine that they are careful and economical of the taxpayers' money.

For example, a board of health, not realizing the value of negative cultures to release diphtheria quarantine, declined to pay a bill for such work, and further refused to spend even the small sum involved in paying the express charges on cultures sent to the laboratory of the State Board in Boston.

The chairman of a local board of health, a physician, was called one day to see a guest at a hotel, and found the patient ill with diphtheria. He informed the patient of the nature of the disease, that he would have to quarantine him, that he would go out and get the cards, etc., and return in an hour or so to put them up. He also informed him that there was a train leaving town within a half hour. his return the patient had departed.

In another instance, in another hotel, the same chairman acted in like manner. In this case, too, a train departed conveniently soon after his first visit. On his return with the cards to establish quarantine

the patient was missing.

As a subject of speculation it might be interesting to inquire whether the towns whither these patients went were notified of these facts as a matter of

courtesy.

At first thought it would seem quite unnecessary to say anything to a body of physicians as to the need of health inspection work in the State, and yet during a brief experience in public health work this very need has been assuming an increasing prominence; indeed, in some ways it is the thing of most importance at this time. Unfortunately, even by physicians themselves, its necessity and value are not sufficiently realized.

There are, for example, physicians like the one who, recently, when asked if he had any cases of measles-none having been reported by him-replied, "Yes, lots of them, but hell, I don't report such cases." Physicians who choose rather to deliberately endanger the community for the sake of currying favor with this or that family by thus enabling them to avoid quarantine restrictions.

One physician said he had been told he need not come again because Dr. X did not put any card on the door for such cases and they preferred to have

In a hotel outside of the State a clerk had scarlet fever. The physician called said the patient could either go home or else he would have to quarantine him there in a hospital. The patient chose to go to his own home in this State, and several cases of scarlet fever followed in his immediate home local-

A physician telephoned that a scarlet fever patient was ready to be released from quarantine. An inspection showed that desquamation was still in

progress on the hands and feet.

Another physician, annoyed by having his release cultures in a case of diphtheria returned positive, took a culture from his own throat, and when that too was reported positive, became more convinced than ever that the whole thing was foolishness, and the work of the laboratory in his opinion was dis-

Another physician decided that a given case was not smallpox, and was said to have advised that other physicians be not called in for fear they would pronounce it such. Seven other unmistakable cases of smallpox in the household later told the story

If physicians who are more or less prominent in their respective localities will do these things, the necessity that they be educated along public health lines is evident.

The conditions thus far pointed out, and the incidents given, all of which are actual occurrences within a comparatively narrow range of observa-tion on the part of a single individual, would seem to indicate unquestionably the need of health inspection work. If each physician could become so impressed with the urgent necessity for public health work that he himself would cooperate heartily with the various health authorities, and impress the importance of this work upon the laymen within his personal circle of influence, it would not be long before a splendid public health service could be built up.

In the abstract the value of individual health is usually recognized, though there are many people who are prodigal and wasteful of health, either through selfish indulgence, or through a feeling of compulsion that certain things must be accomplished regardless of consequences. No argument, however, is usually required to convince an individual that with health he may accomplish much, and that withhealth he may accomplish much, and that out what he may desire.

The value of public health is not so readily appreciated. In the abstract again, any one will admit that it is good and desirable, but that it is worth the expenditure of public money to secure, is quite another proposition. People do not readily see the gain which corresponds to the increased expense.

The funds expended by the street department have substantial results to show in return; witness, paved streets, sidewalks, and gutters. The sewer department with its funds establishes sewers, catchbasins, disposal plants, etc. The water department has reservoirs, miles of pipe, fire hydrants, and the like. So the park, school, and police departments show in various striking and evident ways returns for money expended.

The health department has no such outward results to bring forward for its expenditures. It is charged with the appropriation if perchance there is one, and it has gone largely for services, labor, and supplies, which have left nothing visible to the eye, nothing which shows on the treasurer's books.

This leads to a reluctance to supply this department with funds for much needed work, because it is regarded as a more or less unnecessary expense, as an extravagance, as money wasted on a fad which some radical and visionary people are urging without proper warrant.

In one town a prominent physician informed me that they had no board of health because they werafraid such a board would be a nuisance to the town on account of extravagant and unnecessary ideas they might wish to carry out. People who take this attitude are too much of the opinion that what sufficed for the fathers is good enough for us, evidently forgetful of the changed and changing conditions.

Health inspection work, however, has a very real value, none the less real because it does not appear on the credit side of the ledger. The following instances will perhaps serve to demonstrate somewhat this value.

In one city of less than twenty-five thousand, during a space of two years, there were 176 cases of typhoid fever, an average of eighty-eight each year. During the second of these two years preventive efforts, continued to the present time, were begun by the board of health. During the four years following there were only 120 cases, an average of

thirty each year, a saving of fifty-eight cases annually

If the expense of an illness like typhoid fever, counting loss of wages, expenditures for medical and nursing attendance, and extras of various kinds, is estimated at the extremely moderate sum of \$200, there is a saving of \$11,600 in each year for four years, or a total of over \$46,000, which is a real saving in dollars and cents, and none the less a saving because it does not appear in the financial statement of the city's affairs.

During this current municipal year, now six months advanced, there have been but nine cases of typhoid fever.

This showing of the value, of the profit if you will, of health work would be more striking if the lives saved were taken into account, for during this same series of years 15½ percent. of the cases were fatal. On this basis over forty-five lives have been saved. Surely this is a record to be proud of. The saving on this one disease in any one year has been almost double the entire amount appropriated for the usual work of the board for that year. And this represents only one item in the work such a board carries on.

In another instance, for lack of a proper system permitting the return of a child to school after quarantine, a boy was the means of communicating scarlet fever to thirteen or fourteen other children, two of whom died. The school was closed, and the school house fumigated, thereby entailing a direct loss, the amount of which cannot easily be estimated, which could have been successfully avoided had a suitable system for regulating such things been in force.

Health inspection work has a distinct value also in the affairs of individuals and corporations. I mean a direct financial value aside from its bearing on health, which factor is less easily estimated.

One concern, with thirty employees, situated in the country, had always used outside privies. Less than a year ago suitable modern closets were installed at an expense of over a hundred dollars. The manager assured me that in actual dollars and cents this sum and more had already been returned to him through increased efficiency resulting from the added comfort and healthfulness of his employees.

In another instance, in an establishment where forty men and women were employed the superintendent told me that they were losing at least five dollars every week, because the employees were obliged to go a considerable distance to use very poor privies. This sum has since been saved, for growing out of the inspection came the installation of modern closets.

Many other instances occurring in the course of health inspection work could be cited, but enough have been given to show that health inspection has a very genuine value, which is not generally recognized.

Granting that health inspection work is needful, the question comes, Why should this work be carried on by the State? Why not leave it in the hands of the local boards, which are already clothed with ample authority?

The answer to this question has already been suggested in part in pointing out some of the conditions under which such boards come into existence, and

the character of their members.

Grant further, however, that such boards are well informed about health matters, and that they are reasonably competent. This important fact remains true, that, generally speaking, we are all more or less selfish. Inasmuch as the whole is nothing more than the sum of its component parts, boards of health, too, are all more or less selfish. They are interested chiefly in preserving the health of their own town, and are prone to be not at all interested in the health of other towns, and often make special efforts to hold themselves aloof from cooperative Under such circumstances, though the boundary line is imaginary, and the dwellings continuous, the conditions affecting health existing near the border line within the one town, are rarely made the subject of a message of warning or advice to the authorities of the adjoining town.

One board allowed a case of smallpox to escape to an adjoining town, solely to avoid payment of the expense incidental to caring for the case within their

own borders.

Practically this means numerous boards, each going its own way, along its own lines, subject to no supervision or oversight except in the matter of diseases dangerous to the public health where the State board has coordinate powers with local boards, and in consequence the work is largely haphazard.

Further, the makeup of such boards undergoes frequent and sometimes entire change with each annual election. This is especially true in the case where the selectmen perform the duties of boards of

health.

The newcomers have no more training than their predecessors, and they lack entirely the year's experience which the retiring members have perchance laboriously and awkwardly acquird, and before this board has become really valuable, there is another change.

All these things point convincingly to the need for some means of uniting the various boards and making their work of mutual benefit, to the end that in safeguarding the health of the individual towns and cities, the health of the whole commonwealth may be

equally safeguarded.

The agency through which this should be accomplished is naturally the department of health. There should be the authority to supervise and coordinate through its agents the work of the local boards of health, and the right to force local boards to do any necessary work in case they failed through indifference, ignorance, or unwillingness to maintain the established standard.

Aside from the central authority just mentioned, there are other lesser factors which would aid in

securing an efficient health organization.

Local boards of health should be such, and should be independent of other officials, not identical with them. There would then be no temptation to consider the political effect in carrying out health measures. The only consideration then need be as to what will promote the public health. This point should receive further emphasis because public health is a most valuable asset, to preserve which arbitrary measures are often required, which under

other circumstances would not be tolerated. This means that the best results cannot be attained unless health officials are free to arrive at decisions unhampered by other than considerations of health.

Because health work reaches out in so many different directions, many of which come unexpectedly, some of which cannot be foreseen, and because the judgment of trained and experienced officials is of greater value than that of newly appointed inexperienced officials, there should be increased tenure of office, and members of health boards should be appointed in rotation. The present practice in some towns of appointing one member annually to serve three years should be made uniform. Members should be eligible to reappointment except for cause.

Having secured a health organization, experienced and capable, firmly convinced of the value of health work, various measures employed successfully in places should become uniform in their application.

A hygienic or sanitary history of each case of disease dangerous to the public health would be secured by the physician to the board, the appointment of whom is authorized under our present statutes, or through some properly trained agent.

through some properly trained agent.

This history would show the patient's name, age, residence, civil condition, occupation, school and church attendance, surroundings at home or shop, source of milk and water supplies, previous cases of the same disease in the home or neighborhood, etc.

These records would be kept and tabulated according to circumstances, and such tabulation would quickly suggest special investigation. For example, a second case of scarlet fever or typhoid fever on the same milk route would suggest looking up the dairy which supplied the patients. Two cases of typhoid fever, or even one, would suggest looking up the well, their source of water supply. One or two cases of diphtheria in a school room would suggest a special investigation of the room for a possible mild case of diphtheria untreated or unquarantined.

A system of showing cases of contagious or infectious diseases by houses would soon indicate whether any house was becoming infected, and would suggest a more or less complete renovation

according to circumstances.

To this latter point greater attention should be directed, and less emphasis placed on fumigation. Not that I belittle the process or need of fumigation in any way, but that there are many buildings so encrusted with accumulations of dirt and filth, that fumigation, however thorough, cannot eliminate the danger without renovation as well.

In larger places the provision of contagious disease hospitals should be obligatory, not permissive.

School inspection should not be dependent upon previous appropriation by the town, but should be made obligatory, carried on under uniform regulations adapted to the requirements of city, town, and country schools, rather than according to the varying ideas of each local school or health board.

These are only a few lines along which such work, already begun, may naturally be developed. These and others yet to come will be effective, however, only in proportion as we all come not only to realize their importance, but to act as if we believed them to be necessary, and succeed in impressing this necessity upon those with whom we come in contact.

We must appreciate, too, and insist upon the same

to others, that public health measures are aimed at the good of all, intended to secure for all the greatest measure of freedom in pursuit of their various pleasures and duties, to secure increased productiveness and prosperity, through the doing away with preventable disease, a luxury and extravagance always, which we can ill afford.

141 CHURCH STREET.

Correspondence.

LETTER FROM TORONTO.

The American Hospital Association.—The Training of Nurses.—The Management of Small Hospitals.—Internes and Nurses.—The Growth of the Association.—The Training of Housekeepers.—The Outdoor Work of Children's Dispensaries.—Tuberculosis Clinics.—Hospital Abuses.—Officers for the Ensuing Year.

TORONTO, October 12, 1908.

The tenth annual meeting of the American Hospital Association was held in Toronto during the week ending the 3d of October, under the presidency of Dr. S. S. Goldwater, of Mount Sinai Hospital, New York. There were about 130 delegates registered, and in addition there was a large number of visitors. Many prominent physicians of the United States and Canada were in attendance, among them being the superintendents of most of the larger hospitals in the two countries. The Rev. W. G. Wallace, D.D., of Toronto, opened the convention with prayer, after which the delegates were welcomed to the city by the acting mayor, Comptroller Dr. W. S. Harrison, who suggested that branches of the association be formed in every State and Province, and that these branch associations send delegates to the central organization.

The president, Dr. Goldwater, in his annual address, stated that the membership had doubled in single year, and that the total membership now reached to about five hundred. In his opinion, as membership in the association offered facilities for contact with the guiding minds of some four hundred institutions, it should include trustees, superintendents, and physicians and surgeons. He advocated modification of the organization to provide for a central body with working sections, each with its proper officers, and suggested sections on general administration, medical administration, and ex-

ternal administration.

The problem of training nurses came early before the association and commanded considerable discussion. This culminated in the following resolution presented by Dr. A. S. Kavanagh, of the Methodist Episcopal Hospital, Brooklyn, N. Y.: Resolved: That a committee be appointed, consisting of seven members of this organization, two nurses, two physicians, two laymen, and the president, whose duty it shall be to seek information from leading physicians, surgeons, nurses, and training school committes, and other available sources, bearing upon the curriculum and length of the course of training of our nurses; to consider to what extent hospitals should undertake to prepare a class of hospital nurses or assistants, and to re-

port upon the advisability of cooperating with such associations as the Young Women's Christian Association in the work; to present a model curriculum containing only such subjects as they think necessary for the proper training of a regular nurse or a nurse helper; and to report at the next annual meeting of the association. The sum of \$500 was appropriated to defray the expenses of the committee in gathering the information for their report.

A Layman's View of Hospital Work was the title of an interesting paper read by Mr. John Ross Robertson, chairman of the Trustees of the Hospital for Sick Children, Toronto. Mr. Robertson said that during the past thirty years hundreds of thousands of dollars had been received in voluntary contributions for the hospital represented by him. An intimate knowledge of the resources which sustained the work at this hospital showed that the dollars and dimes of the many were received rather than large donations from the wealthy; hence the millionaire and his money were not soon parted in this work.

In a paper on Problems in the Management of Small Hospitals, Dr. Theodore R. MacLure, of the Solvay General Hospital, Detroit, hospitals with fewer than fifty beds were dealt with. Dr. MacLure said that one of the hardest problems to deal with was the weakness of internes and nurses, showing that it was harder to keep the nurses away from the internes than it was to keep the internes away from the nurses. Another difficulty encountered was the egotism of young doctors, who, though they had just received their degrees, thought they knew everything there was to know about hos-

pital work. The Committee on the Development of the Association reported that 238 applications, of which sixtyfive were from trustees and members of hospital boards, had been received during the year. State of New York headed the list, with sixty-five applications, and Canada was credited with twentyfive. This committee suggested combining the offices of secretary and treasurer, with a renumeration, and the incorporation of the association. It was shown that the work of the association had developed to such an extent that in a few years it would dominate the entire hospital world in the United States and Canada. The treasurer's report showed receipts, including a balance of \$624.24 from 1907, of \$2,412.64, and disbursements of \$1,-143.74, leaving a balance of \$1,268.64.

Miss M. U. Watson, director of the Home Economic Department of the Macdonald Institute, in Guelph, Ont., gave an interesting talk on Trained Housekeepers. She pointed out that the training of housekeepers was at present in the initial stage, just as the doctor, the nurse, and the librarian had

to go through their initial training.

Field Work in Connection with Children's Dispensaries was the title of a paper by Robert W. Bruere, general agent of the New York Association for Improving the Condition of the Poor. He said that this branch of hospital work was of wide scope from the standpoints of health, public morals, and society. The field work was relatively of the same nature and effect among the poor as that of a Red

Cross corps among soldiers on the battlefield. The physical and social conditions were brought together by this medium under circumstances that differed from those of other occasions.

Dr. James Alexander Miller, president of the Association of Tuberculosis Clinics, of New York, in speaking on the subject of cooperation in dispensary work as exemplified by the Association of Tuberculosis Clinics of New York, dealt almost exclusively with the phase relative to educating people in the home as to the dangers of tuberculosis and

its treatment.

Then followed a discussion on the development of the work and restriction of the abuse of the out patient department. The discussion was closed by Mr. J. Ross Robertson, of Toronto, who made a few remarks from a local standpoint on the Hospital for Sick Children. According to him, the present indications were that some 8,000 to 10,000 people would be seeking assistance for their children. A few years ago they had discovered a large amount of imposition, but they had appointed an agent and this had to a great extent been remedied.

On the reformer, the man who was always job hunting, Dr. D. C. Potter, Chief of the Charitable Institution Division, Department of Finance, New York, came down pretty hard. On "grafters" he was particularly severe; woe unto the hospital where the reformer installed himself with the avowed purpose of economically administering its affairs. Under him there were sure to be changes which would involve dear fresh air, while fresh bandages would be an impossibility. There was no hippodrome of mirth so funny or so senseless as the general run of city governments, and sometimes they were tragic. The Canadian girls who went to the training schools of the United States he considered splendid types of young womanhood, and they became the best of good nurses.

The question of controlling infectious and contagious diseases was thoroughly gone into. Since 1802 it had cost the Hospital for Sick Children, Toronto, \$15,000 to \$20,000 by infection brought into the institution by people visiting the patients. This was corroborated by many of the delegates, who

stated they had a similar experience.

Dr. Donald McIntosh, of the Western Infirmary, Glasgow, who is making a tour of the hospitals of the United States and Canada, was made an honorary member of the association. He said he had gleaned valuable information in America, but he had yet to find a perfect hospital, even though he

had been in the United States.

Washington, D. C., was selected as the place of meeting in 1909, the time appointed being from September 22d to the 29th inclusive. Mr. Robertson was offered the presidency unanimously, but declined the honor. The following officers were elected: President, Dr. John M. Peters, of the Rhode Island Hospital, Providence, R. I.; vice-presidents, Dr. Arthur A. Aucker, of the City and County Hospital, St. Paul, Minn., Dr. J. N. E. Brown, of the Toronto General Hospital, and Miss Emma Henderson, of the New England Baptist Hospital, Boston; secretary, Dr. W. L. Babeock, of Grace Hospital, Detroit; treasurer, Dr. Asa Bacon, of the Presbyterian Hospital, Chicago.

Therapeutical Rotes.

The Use of Arsenic in Anæmia.—Lemoine, of Lille, while speaking on the treatment of anæmia in Le Nord médical, advises, among others, the following arsenic preparations:

| | 0 | | | 7 | 1 | | | | | | | | | | | | | | | | | |
|----|----|--------|------|------|-----|------|-----|----|-----|----|-----|----|----|----|---|----|---|-----|----|----|-----|---|

| | | | | | | | | | | | | | | | | | | | | | | |

Vapor Compound for Use in Bronchitis of Infants.—In the treatment of bronchitis in infants it is recommended (Journal de médecine de Paris, September 26, 1008) to evaporate in the room three or four times daily a teaspoonful of the following solution added to five ounces of water heated in a teapot or a special vaporizer:

Wood creosote, 5i;
Tincture of benzoin, 3ii;
Oil of turpentine, 3iiss.

M.

Pruritus Senilis.—Levy remarks in the Berliner klinische Wochenschrift, September 28, 1908, that Leo, Köhler. and Ströll state in the Therapeutisches Jahrbuch, that it is possible to relieve, and very often to cure, pruritus senilis by the following:

B Diluted sulphuric acid, 5.0 grammes;
Distilled water, 175.0 grammes;
Syrup of rubu 30.0 grammes.
M. S. One tablespoonful every two hours.

A Lotion for Cracked Nipples.—Marfan remarks that the greatest care should be given to the dressing of tracked nipples, which should be washed with the following:

| F. | Rose water, | | | | | | .gr. xl; |
|-----|-------------------|-----|------|------|------|------|------------|
| | Glycerin, | | | | | | .gr. xx; |
| | Sodium borate, | | | | | | .gr. viii; |
| 2.5 | Tincture of benzo | iπ, | | | | | gr. xii. |

Diagnosis and Treatment of Fistulous Ducts.

—Beck (Zentralblatt für Chirurgie) injects through the opening of a fistula with a glass syringe and under very moderate pressure the following:

| | | G |
|--------------|---------------------|----------|
| \mathbf{R} | Bismuth subnitrate, | gr. xxx; |
| | White petrolatum, | gr. lx; |
| | Paraffin, | gr. 5; |
| | Wax, | gr. v. |

He then takes a radiograph of the region injected and thus obtains a complete representation of the

The author has used this method in a number of cases, and always with success. In one of his cases the patient suffered for nine months from an empyema of the thorax, which discharged 120 grammes of pus in twenty-four hours, and the fistula had resisted all other treatments. It had been decided to subject the patient to the Estlander operation, but the author, as a last resort before surgical interference, wished to try his injection. After the twentieth injection the fistula closed and had not opened again at the time of the last examination, three months after it had closed.

NEW YORK, SATURDAY, OCTOBER 24, 1908.

TROPICAL DISEASES IN THE UNITED STATES.

The American Society of Tropical Medicine has done much to arouse among us a proper interest in the diseases with which it deals, and much more may be expected from its further work. An additional impetus in the same direction is likely to be the result of the very scholarly oration in medicine delivered before the thirty-fourth annual meeting of the Mississippi Valley Medical Association, held recently in Louisville, by Dr. George Dock, of New Orleans, formerly of Ann Arbor, Mich. The address is published in the Lancet-Clinic, of Cincinnati, for October 17th.

In the early part of the address Dr. Dock paid a richly deserved tribute to the genius of Dr. Daniel Drake, whose monumental treatise on the diseases of the Mississippi Valley was one of the most conspicuous and valuable features of the American medical literature of the first half of the nineteenth century, quite equal in value to Dr. Elisha Bartlett's work on the fevers of the United States. Not the least of Dr. William Osler's great services to American medicine during his stay in this country was that of pointing out anew to us the value and undiminished utility of such books. In this age of rushing progress we are far too apt to overlook the work of those who have gone before us, forgetting that, though our predecessors had not at their command the full array of facts with which we of the present day are favored, their discernment and their critical power were such as most of us might envy.

Coming to his subject proper, Dr. Dock gave a masterly survey, though in general terms of course, of malarial diseases, amœbic dysentery, yellow fever, uncinariasis, Malta fever, dengue, spirillar fever, the Oriental plague, and pellagra. He properly pointed out that a disease might correctly be termed tropical even if its ravages were not confined to the tropics; it was only necessary, he said, that it should flourish in those regions preponderatingly. Not all of the diseases mentioned have ever prevailed in the United States to a serious extent, and we are not aware that Malta fever has been recognized here at-all, though Dr. Dock thinks that the conditions are favorable for its development in the Mississippi Valley. Others, such as uncinariasis, pellagra, and amœbic dysentery, however, must have flourished long before they were recognized. This is especially true of uncinariasis, for our present knowledge of which, especially as regards its ætiology, we are deeply indebted to a zoologist, Professor Stiles. Fortunately the disease is easily curable, and we may hope to see it virtually eradicated, especially as Dr. Dock tells us that Professor Stiles himself has entered anew upon a survey of the conditions which favor its diffusion. It has been a veritable menace to the welfare of our people in the southern States and a still greater source of peril in one of our new possessions, Puerto Rico.

Dr. Dock earnestly recommends the systematic study of tropical diseases as one of the features of our college curricula, and it certainly seems that the medical schools of the country must give particular attention to the new branch, as is now done in the medical schools of the army and navy. Of course it is true that tropical medicine is not wholly a new thing, but it is only within the last few years—since the war with Spain, we might say—that it has taken any pronounced hold of professional attention in the United States. If we are late to enter the field, let us at least put forth our best endeavors to make up for lost time.

A SUPPOSED PROTECTIVE INFLUENCE OF BOVINE TUBERCULOUS INFECTION.

In a paper read at the recent International Congress on Tuberculosis, an abstract of which will be found in the installment which we publish this week of the proceedings of the sections, Dr. Nathan Raw, of Liverpool, brought forward an idea that may yet be turned to advantage in the struggle against pulmonary consumption, provided further observation

shows it to be substantially founded. Dr. Raw's hypothesis is that infection with the bovine variety of the tubercle bacillus is generally productive of one of the "surgical" forms of tuberculous disease, and rarely if ever of the pulmonary form, also that the bovine infection has a tendency to confer immunity against the attacks of the human variety of the bacillus.

Lupus and the so called scrofulous glands of our older literature are among the diseases which Dr. Raw attributes to the bovine bacillus. Tuberculous glands might be tolerated if we were to become convinced of their playing such a part as that with which he credits them, but lupus is serious enough in itself to make it an unwelcome ally in the prevention of consumption, and the other affections imputed by the author to bovine infection are still more to be dreaded. If it comes to be established that these forms of tuberculous disease are really indicative of an infection which is antagonistic to the action of the human bacillus, it will be important to learn, further, whether it is their existence per se that is operative, or whether the general infected condition, of which they are only manifestations, is what we may depend upon. Upon this further knowledge would hinge the question of whether or not it was judicious to undertake the cure of tuberculous glandular disease.

Of course, what we have alluded to was not Dr. Raw's main contention, but rather the proposition that many forms of tuberculous disease were due to infection with the bovine variety of the tubercle bacillus. All of them are serious, and we may well join the author in calling for the observance of every possible precaution to prevent infection from cattle. The vexed questions of the relations between tuberculous disease in the human and in the bovine subject has been endowed with a new aspect by Dr. Raw, one that, we may suppose, will stimulate further research.

THE MORTALITY FROM TUBERCULOUS DISEASE IN THE UNITED STATES.

Among the data prepared for the use of the recent International Congress on Tuberculosis was an exceedingly instructive pamphlet, prepared by Dr. Cressy L. Wilbur, chief statistician for vital statistics of the Burcau of the Census, entitled *Tuberculosis in the United States*. Dr. Wilbur, who is a very careful writer, takes up many aspects of the subject. Not the least important of them is one which he deals with under the heading of Understatement of Tuberculosis in Returns of Deaths. He remarks that there is a large margin of possible error and probably of understatement in the recorded

deaths from tuberculous disease even in the registration area, and he asks how many deaths from pulmonary tuberculous disease have been reported as due to "heart failure," "congestion of lungs," "debility," "inanition," "marasmus," and the like.

He states that many deaths ascribed to "chronic bronchitis" and "bronchopneumonia" are really due to tuberculous infection. He cites Osler as maintaining that a majority of the cases of acute serofibrinous pleurisy are tuberculous, and adds that many of the deaths certified to as due to "hæmorrhage," practically all of those accounted for by "hæmorrhage of the lungs," are deaths of tuberculous persons, and that deaths from pulmonary tuberculous disease are concealed by the use of such terms as "lung trouble," "heart disease," etc. He says that, according to Dr. J. W. Irwin, physician to the Henry Phipps Institute, of Philadelphia, deaths attributed to abscess of the chest, hip, or lungs; iliac, lumbar, pleural, or psoas abscess; asthma; congestion of the brain, chest, or lungs; debility; disease of the brain, chest, hip, or lungs; dropsy of the brain, chest, or lungs; empyema; brain fever; inflammation of the brain, hip, or larynx; marasmus; tabes mesenterica. etc., are probably due to tuberculous disease. Among the deaths that the same writer thinks may possibly be owing to tuberculous disease are those imputed to cachexia; cerebrospinal meningitis; cholera infantum; convulsions; cyanosis; diarrhœa; diseases of the spine; typhoid fever (a certain proportion); inflammation of the bronchi, chest, lungs, peritonæum, pleura, spine, stomach, or bowels; influenza; teething; and whooping cough. Dr. Irwin's statements had reference only to the causes of death registered in Philadelphia.

Many of the misleading certificates argue ignorance almost inconceivable on the part of registered physicians, and a few are probably due to the difficulty of making a diagnosis in certain forms of tuberculous disease, but Dr. Wilbur suspects that there may in some instances be an element of intentional deception. The following reasons for the deception are suggested: The physician may have neglected to fulfil a legal requirement to report the illness as tuberculous in its nature, and in that case he would show himself to have violated the law if he reported the death correctly; the record of a death from tuberculous disease might conflict with representations contained in applications for life insurance made by persons closely related to the deceased; or the report of the true nature of the trouble may simply be "thought undesirable" by the

But, taking the returns as they stand, with all their defects, we still have to count tuberculous infection as giving rise to 11.2 per cent. of the entire mortality, a proportion greater than that caused by any other disease. This is graphically shown by a frontispiece which represents the following proportions: All forms of tuberculous disease, 11.2; all forms of pneumonia, 9.8; heart disease, 8.6; violence, 7.6; diarrhœa and enteritis, 7.1; nephritis and Bright's disease, 6.4; apoplexy, 4.6; cancer, 4.4; congenital debility, 2.2; premature birth, 2.2; ill defined causes, 2.1; old age, 2; bronchitis, 1.9; typhoid fever, 1.8; meningitis, 1.6; diphtheria and croup, 1.5; paralysis, 1.2; cirrhosis of the liver, 1; convulsions, 1; whooping cough, 0.7; and all other causes, 21.

THE CELL FORMULA OF THE LYMPH.

It is the general opinion among hæmatologists that the lymphocytes are furnished to the peripheral blood from the lymph nodes, through the lymphatic vessels, and that the other varieties of the leucocytes have their origin in the red bone marow, and reach the blood stream directly through the efferent veins from the marrow. There is much difference of opinion in regard to the origin of the large uninuclear leucocyte, some observers believing that it originates in the lymph nodes, others that it is produced in the bone marrow, and still others that it is the product of both tissues. There is the theory, furthermore, that these cells result from the desquamation of the endothelial cells lining the bloodvessels. The composition of the lymph is very indefinitely understood, and a contribution to our knowledge of its morphology by Dr. F. Peyton Rous (Journal of Experimental Medicine, July) is welcome. By making smears of the lymph in the usual way, and employing one of the tinctorial methods in general use in hæmatology, the author has been able to represent very definitely the character of the cells found in that fluid as it flows from the mouth of the thoracic duct in dogs. Lymphocytes form 87.6 per cent. of the cells found in the lymph taken as above indicated. The large uninuclear cells constitute an average of 5.2 per cent., and the eosinophile cells form 2.6 per cent. of the cellular elements. Mast cells were not seen; polymorphonuclear neutrophile cells were found only when the lymph was mixed with blood, and typical transitional elements were rare.

The eosinophile cells in the lymph were found to vary very much in number. In one instance they formed twelve per cent, of the total number of white cells. When food was withheld from the animal they became fewer, while on a mixed diet in which meat preponderated they increased in number. They did not seem to be influenced by the presence of intestinal parasites, of which a careful record was kept.

The number of transitional leucocytes found in the lymph and the number found in the circulating blood of the dog do not coincide at all; the cells are very rare in the lymph, but abundant in the blood. For example, in one of the animals there were no transitional cells in the lymph in 550 cells counted, while there were twenty-five in the blood in 311 cells counted, 8.03 per cent. Numerous observations of this kind would tend to show that the transitional leucocytes are not furnished to the peripheral blood through the thoracic duct. The comparison of the number of large uninuclear leucocytes in the lymph and in the peripheral blood gives similar but not such striking results. The relation of large uninuclears to the lymphocytes in the lymph was one to seventeen; in the peripheral blood, one to 4.4. The author is of the opinion, however, that this fact does not necessarily mean that the large uninuclear form is derived from other lymph elements in the blood or that it has its source outside the lymph. His reasons for this opinion are that the lymph does add a considerable number of large uninuclear cells to the blood; that these cells may persist in the blood longer than the lymphocytes, and so accumulate; and that there are certain technical difficulties in diagnosticating between the large and the small uninuclear elements.

PLAGUE IN THE UNITED STATES.

Under the heading "Danger!" Collier's Weekly for October 10th has a leading editorial on the plague situation in California, the gist of which is that the ground squirrels in the country about the region of San Francisco Bay have been found to be infected with plague, and that the business interests in Oakland are trying to conceal the truth, at the same time that they refuse to appropriate money for a suitable antiplague campaign.

The facts about plague in California are these: There was an epidemic in San Francisco in 1806, which was denied by the business interests of that city for the sake of the prevention of possible pecuniary loss. This epidemic and the attendant friction between the city, State, and federal authorities resulted in the resignation of an efficient officer, Dr. J. J. Kinyoun, from the United States Public Health and Marine Hospital Service, in the loss of many lives, and in the propagation of an epizootic among the rats in San Francisco. This epizootic, in turn, led to an insignificant epidemic among the inhabitants, which was confined practically to one quarter of the city. On May 23, 1907. a case of bubonic plague was discovered in the person of a sailor on a coastwise tug, and since that time there have been 159 cases of plague in San 800

Francisco, with seventy-seven deaths, besides fatal cases in Oakland, Cal., Seattle, Wash., and other California cities and towns. In 1907 Rucker (Journal of the American Medical Association, February 23d) maintained that Currie had found wild ground squirrels infected with plague. This observation has now been confirmed by Blue, by McCoy, and by Wherry (Public Health Reports. September 11th).

Through the excellent work of Dr. Blue and his associates there has been no case of human plague in San Francisco since January 30th. A plague rat is trapped at infrequent intervals, however. In other parts of the Pacific coast human plague and rat plague are still present. There was a case of human plague in Los Angeles on August 11th. A plague rat was trapped in Seattle on September 26th (Public Health Reports, October 9th).

In view of these facts we would remind the citizens of California of two old proverbs: "Honesty is the best policy" and "A stitch in time saves nine."

Rems Items.

The Tri-State Medical Association of Arkansas, Lou-

isiana, and Texas will meet in annual session in Texarkana, Ark., on November 11th.

The Southern Medical Association.—The second annual meeting of this association will be held in Atlanta, Ga., on Tuesday, Wednesday, and Thursday, November Ga., on Tuesday, Toth, 11th, and 12th.

Reception to Dr. John B. Murphy.—The Medical Club of Philadelphia gave a reception at the Bellevue-Stratford on the evening of October 16th, in honor of Dr. John

Murphy, of Chicago

The Boston Society of Examining Physicians.-The

The Boston Society of Examining Physicians.—The winter season of this society was opened on the evening of October 21st by a dinner at the Boston City Club. Dr. Francis Donoghue presided. Addresses were made by Dr. Morton Prince and Dr. Richard C. Cabot.

The Harvey Society Lectures.—The first lecture in the course of 1908-1909 will be delivered on Saturday, October 24th, at 8:30 p. m., at the New York Academy of Medicine, by Professor A. Calmette, of the Institut Pasteur de Lille, France, on Intestinal Infection and Immunity in Tuberculosis

Buffalo Academy of Medicine.—A special meeting of the academy will be held on Tuesday evening, October 27th, under the auspices of the Section in Obstetrics and Gynecology. The topic selected for discussion is ectopic pregnancy, and the paper of the evening will be read by Dr. Herman E. Hayd.

A Gift to the Presbyterian Hospital, New York .-A Gift to the Presbyterian Hospital, New York.—
Mr. John S. Kennedy, the New York banker and philanthropist, celebrated his golden wedding anniversary on
October 14th by making a gift of \$1.000.000 to the Presbyterian Hospital. The money will probably be used to
build a new administration building.
Scientific Society Meetings in Philadelphia for the
Week Ending October 31, 1908:

Mor 10.10 October 31, 1908:

Mos Section, Academy of Natural Sciences.
TURSDAY, October 27th.—Medicolegal Society.
Will all Physics County Medical

The Holyoke, Mass., Medical Society.—At a recent meeting of this society the following officers were elected to serve for the ensuing year: President, Dr. G. L. Gabler; vice president, Dr. T. E. Cavanaugh; secretary and treasurer, Dr. I. H. Farr; executive committee, Dr. G. L. Taylor, Dr. G. H. Cox. and Dr. J. J. Carroll.

An Emergency Hospital in the Waldorf-Astoria.-It is reported that an emergency hospital, the first of its kind in New York, has been opened in the Waldorf-Astoria. It is in a basement room and is well equipped with all necessary appliances. Dr. Calvin Thayer Adams and Dr. Robert Adams, house physicians of the hotel, are in

Contagious Diseases in Chicago.—During the week ending October 10, 1908, the following cases of contagious diseases were reported to the Department of Health: Diphtheria, 121 cases; scarlet fever, 94 cases; measles, 12 cases; chickenpox, 2 cases; pneumonia, 15 cases; typhoid fever, 61 cases; whooping cough, 11 cases; tuberculosis, 15 cases; diseases of minor importance, 4 cases; total, 335 cases.

diseases of minor importance, 4 cases; total, 335 cases.

Richmond, Va., Academy of Medicine and Surgery.—

A regular meeting of this academy was held on the evening of October 13th. Dr. W. L. Peple read a paper on the Diagnosis and Treatment of Tuberculosis of the Testicle, which was discussed by Dr. R. C. Bevan. Dr. Lewis C. Bosher read a paper entitled Diagnosis and Treatment of Suppurative Bone Disease, and the discussion on this paper was opened by Dr. William P. Mathews.

Examination for Internes at the City Hospital .- An examination will be held at the City Hospital, Blackwell's Island, New York, on Saturday, November 7th, at 130 p. m., of candidates for positions on the house staff of the hospital. Candidates are requested to submit their credenitals and to apply for further information regarding the examination to Dr. Joseph Collins, chairman of the Examination Committee, 37 West Fifty-fourth Street, New York.

The Mississippi Valley Medical Association.—At the

The Mississippi Valley Medical Association.—At the annual meeting of this association, which was held recently in Louisville, Ky., the following officers were elected: President, Dr. J. A. Witherspoon, of Nashville; first vice president, Dr. Louis Frank, of Louisville; second vice president, Dr. A. E. Sterne, of Indianapolis; secretary, Dr. Henry E. Tuley, of Louisville; treasurer, Dr. S. C. Stanton, of Chicago. St. Louis was chosen as the next place of tractions. meeting

Dr. Spratling Honored .- To commemorate the labors of Dr. William P. Spratling, who directed the work of the Craig Colony for Epileptics, Sonyea, N. Y. for fourteen years, the board of managers of that institution recently years, the board of managers of that institution recently passed a resolution naming the executive building Spratling Hall. Dr. Spratling recently resigned his position as medical superintendent of the institution to accept the chair of nervous diseases and physiology at the College of Physicians and Surgeons, Baltimore.

The New Corps of Women Nurses in the Navy.—

The recent examination of candidates for appointment in the naval hospitals resulted in the selection of sixteen women nurses, who have been ordered to report for duty at the Naval Medical Hospital, Washington, D. C., where for the next six months they will be under instruction as to the special duties required of them as naval nurses. At the end of this time they will be assigned to the naval hospitals at Yokohama, Canacao, and San Juan, Puerto Rico,

Army Commissions for Philadelphia Physicians.—

Army Commissions for Philadelphia Physicians.—Announcement has been made that a number of prominent physicians and surgeons of Philadelphia have been appointed first lieutenants of the Medical Reserve Corps of the United States Army. The commissions do not carry a salary with them, but they hold the recipient available for service in case of war. Among those who have received commissions are Dr. John B. Deaver, Dr. Francis D. Patterson, Dr. J. Chalmers Da Costa, Dr. Edward Martin, Dr. John G. Clark, Dr. Hobart Amory Hare, Dr. G. E. de Schweinitz, Dr. J. William White, and Dr. Charles B. Penrose

Penrose
The Mortality of Chicago.—During the week ending
October 10, 1908, there were reported to the Department
of Health of the City of Chicago 503 deaths from all causes, as compared with 518 for the previous week, and 498 for the corresponding period in 1907. The annual death 498 for the corresponding period in 1907. The annual death rate, in an estimated population of 2,166.055, was 12.10 in 1,000 of population. Of the total number of deaths 171 were of children under five years of age. The principal causes of death were: Apoplexy, 12 deaths; Bright's disease, 46 deaths; bronchitis, 11 deaths; consumption, 53 deaths; cancer, 29 deaths; diphtheria, 11 deaths; heart diseases, 39 deaths; intestinal diseases, acute, 116 deaths; nervous diseases, 15 deaths; pneumonia, 34 deaths; searlet fever, 5 deaths; suicide, 8 deaths; typhoid fever, 3 deaths; violence (other than suicide), 32 deaths; whooping cough, a deaths; all other causes, 87 deaths.

The Elmira, N. Y., Academy of Medicine.-A special meeting of the academy was held on the evening of Wednesday, October 21st, to celebrate the opening of the new rooms in the Federation Building, corner of Church and State streets. The programme included the following and State streets. The programme included the following papers: Clinical Manifestations of Uræmia, by Dr. Henry C. Bushwell, of Buffalo; The Nervous Child, by Dr. Henry L. K. Shaw, of Albany; Psychotherapy, by Dr. Edward B. Angell, of Rochester. The present officers of the academy are: President, Dr. R. G. Loop; vice president, Dr. A. J. Westlake; treasurer, Dr. C. G. R. Jennings; secretary, Dr. F. L. Christian.

Society Meetings for the Coming Week:

Monday, October 26th.—Medical Society of the County of New York (annual).

Tuesday, October 27th.—New York Dermatological Society; Metropolitan Medical Society of New York City; Buffalo Academy of Medicine (Section in Obstetries and Gynæcology).
Wednesday, October 28th.—New York Academy of Medi-

cine (Section in Laryngology and Rhinology); New

York Surgical Society.

York Surgical Society.

Thursday, October 20th.—Brooklyn Society of Neurology.

Changes of Address.—Dr. William P. Spratling, formerly medical superintendent of the Craig Colony for Epileptics, Sonyea, N. Y., to 1110 North Charles Street, Baltimore Med. leptics, Sonyea, N. Y., to 1110 North Charles Street, Lindon, Dr. W. E. Hays. to 500 West One Hundred and Forty-fourth Street, New York.
Dr. Arthur B. Duel and Dr. John Randolph Page, to 27 East Fifty-seventh Street, New York.
Dr. S. Mason McCollin, to 1725 Arch Street, Philadel-

Dr. William P. Grady, to 1214 North Seventh Street,

The Tri-Professional Medical Society of New York held its nineteenth stated meeting on Tuesday evening, October 20th. Interesting cases and specimens were presented by Dr. Walter T. Dannreuther, Dr. Augustin H. Goelet, and Dr. B. S. Talmey. Dr. George M. MacKeerad a paper entitled Fulguration—A Special Method of Academic that Utils Tectures of Social Method of Section 1988. Applying the High Frequency Spark in the Treatment of Certain Diseases. Dr. I. L. Hill read a paper on Version, and reported fifty cases. Among those who participated in the discussion were Dr. William H. King, Dr. William H. Dr. William H. Dr. William H. King, Dr. William H. Dieffenbach, Dr. Augustin H. Goelet, Dr. Ross Mc-

Pherson, and Dr. Edward S. Gushee.

Personal.—Dr. William Seaman Bainbridge, of New York, returned from Europe on October 23d. Dr. Bainbridge attended the Second International Surgical Con-

gress, which met in Brussels in September.

Dr. Roswell Park, of Buffalo, returned recently from an extensive European trip. He attended the Second International Surgical Congress in Brussels, of which he is

the American representative on the executive committee.

Dr. Henry Asbury Christian, Hersey professor of the theory and practice of medicine at Harvard Medical School, and physician in charge of Carney Hospital, Boston, has been elected dean of the medical faculty. Dr. Christian is collected that the control of the medical faculty.

is only thirty-two years of age

American Hospital Association .- At the annual meeting of this association, which was held recently in Toronto, the following officers were elected to serve for the ensuing the following officers were elected to serve for the ensuing year: President, Dr. John M. Peters, of Providence, R. I.; first vice-president, Dr. Arthur B. Aucker, of St. Paul, Minn.; second vice-president, Dr. J. N. E. Brown, of the Toronto General Hospital; third vice-president, Miss Emma A. Anderson, of the New England Baptist College, Boston; secretary, Dr. W. L. Babcock, of Grace Hospital, Detroit, reelected; treasurer, Dr. Asa Bacon, of the Presbyterian Hospital, Chicago, reelected. Dr. Donald J. M. Schirteche superirendent of the Western Informary Glass Mackintosh, superintendent of the Western Infirmary, Glasgow, was elected an honorary member of the association.

The Philadelphia Academy of Surgery.-The following programme was presented at a meeting of this academy which was held on Monday evening, October 5th: Dr. William L. Rodman: (a) Exhibition of a case of americ dysentery cured by appendicostomy, (b) report of a case of secondary hæmorrhage from the popliteal artery, (c) exhibition of a specimen of a large exophthalmic goître; Dr. Charles F. Nassau: Report of three cases of gunshot wound of the abdomen, with the exhibition of patients; Dr. John H. Jopson: Report of three cases of gunshot wound of the abdomen; Dr. George G. Ross: Paper entitled Some Experiences in Removing the Vermiform Appendix in

Cases that had been operated upon; Dr. Edward Martin: Report of a case of shock and bleeding treated by the intravenous injection of twelve pints of normal salt solution; Dr. Charles H. Frazier; The exhibition of a new operating

The East Side Physicians Association.—The October meeting of this organization was held on Thursday evening, October 15th. Dr. George Friedmann presented a patient with bronze diabetes. A case for diagnosis was presented by Dr. Max Ghertler, and Dr. William S. Gottheil presented a patient with lepra tuberosa. Dr. S. Solis-Cohen, of Philadelphia, read a paper entitled Some of the Principles Governing the Use of Drugs in the Treatment of the Sick. Dr. Henry Illoway read a paper Treatment of the Sick. Dr. Henry Howay tead a page-on Muscular Rheumatism, which was followed by a gen-eral discussion. The officers of the association are: Presi-dent, Dr. Henry Illoway; first vice president, Dr. Morris Cisin; second vice president, Dr. George Dow Scott; sec-retary, Dr. Sigmund Epstein; treasurer, Dr. I. Seth Hirsch.

Infectious Diseases in New York:

We are indebted to the Bureau of Records of the De-partment of Health for the following statement of new cases and deaths reported for the two weeks ending October

Charitable Bequests.—By the will of Grace M. Kuhn, Harvard University receives \$175,000 to endow a department of biological chemistry, in memory of a son, Hartman Kuhn, who died several years ago. The Massachusetts General Hospital receives \$10,000 for the clinical

By the will of Mrs. Martha W. Collard, who died in Europe last spring, the New York Home for Aged People, the New York Society for the Ruptured and Crippled, the Newport, R. I., Hospital, and the Presbyterian Hospital, New York, will each receive 100 shares of capital stock of the Standard Oil Company, in each case to be called the Fiske Fund

The Orphan Asylum Fund of Paterson, N. J., has been increased by a contribution of \$5,000 from Mrs. Jennie T.

The Medical Society of the County of New York. The Medical Society of the County of New York.—
Astaed meeting of this society will be held in Hosack Halt
of the New York Academy of Medicine on Monday evening, October 26th. The programme will consist of a "sympositum" on opsonic therapy. Papers will be read as follows: Opsonins, Opsonic Index, and Immunity, by Dr.
Eugene L. Opie, of the Rockefeller Institute for Medical
Research: The Treatment of Erysipelas by Bacterial Vaccines, by Dr. George W. Ross, of Toronto; The Therapeutic Value of the Onsonic Index in Pulmanary Tubergucines, by Dr. George W. Ross, of Toronto; The Thérapeutic Value of the Opsonic Index in Pulmonary Tuberculosis, by Dr. Gerald Bertram Webb, of Colorado Springs; The Production and Estimation of Phagocytic Immunity, by Dr. J. C. Meakins, of New York; The Use of Vaccines in Gonococcus and Streptococcus Infections, by Dr. Nathaniel Bowditch Potter, of New York. Among those who will take part in the discussion are Dr. William H. Park, Dr. Norman E. Ditman, and Dr. C. G. Coakley. r. Norman E. Ditman, and Dr. C. G. Coakley. Vital Statistics of New York.—During the week end-

ing October 10, 1968, there were reported to the Department of Health of the City of New York 1,223 deaths from all causes, of which 601 were in Manhattan, 103 in The Bronx, 416 in Brooklyn, 75 in Queens, and 28 in Rich The Bronx, 416 in Brooklyn, 75 in Queens, and 28 in Richmond. The annual death rate in 1,000 of population was 14.43 for the whole city, 13.67 for Manhattan, 16.40 for The Bronx, 14.54 for Brooklyn, 16.82 for Queens, and 19.05 for Richmond. During the corresponding period in 1907 the total deaths numbered 1,344, with an annual death rate of 16.36 in 1,000 of population. Of the total number of deaths 402 were of children under five years of age, and of these 163 were due to diarrhead diseases. There were of these 163 were due to diarrhœal diseases. 84 violent deaths, of which 65 were from accidents, 5 from homicide, and 14 from suicide. One hundred and thirty-seven still births were reported. There were 2,150 births and 772 marriages reported during the week.

The Fifth District Branch of the Medical Society of the State of New York, which comprises the members of the medical societies of the counties of Onondaga, Oneida, Herkimer, Oswego, Lewis, and Jefferson, held its second annual meeting in Utica, N. Y., on October 15th. Officers to serve for the ensuing year were elected as follows: President, Dr. G. D. Gregor, of Watertown; first vice president, Dr. F. E. Fox, of Fulton; secretary, Dr. W. D. Garlock, of Little Falls; treasurer, Dr. F. E. Jones, of Beaver Falls. Watertown was selected as the next place of meeting.

Medical Inspection of Schools in Chicago.-During the week ending September 26, 1908, the total number of school children examined by the school medical inspectors was 21,429, and of these 536 were excluded on account of contagious diseases. Physical examinations were made by the inspectors of 4,195 school children, and of these 3,381 were found defective and 1,919 advised to seek treatment. Defects were found distributed as follows: Nutrition, 97; anæmia, 95; enlarged glands, 43; nervous diseases, 7; cardiac diseases, 35; pulmonary diseases, 21; skin diseases. 27; orthopædic, 27; vision, 649; hearing, 100; nasal breathing, 134; palate, 24; teeth, 1,215; hypertrophied tonsils, 750;

adenoids, 129; mentality, 35.

Vital Statistics of New Jersey.—The total number of deaths reported to the Bureau of Vital Statistics of the State of New Jersey for the month ending September 15. 1908, was 3,464. The principal causes of death were: Typhoid fever, 45 deaths; measles, 9 deaths; scarlet fever, 7 deaths; whooping cough, 38 deaths; diphtheria 23 deaths; malarial fever, 3 deaths; pulmenary tuberculosis, 272 deaths; other forms of tuberculosis, 59 deaths; cancer, 134 deaths; cerebrospinal meningitis, 26 deaths; diseases of the nervous system, 385 deaths; diseases of the circulatory system, 315 deaths; diseases of the respiratory system (pneumonia and tuberculosis excepted), 112 deaths; pneumonia, 103 deaths; infantile diarrhœa, 699 deaths; diseases of digestive system, (infantile diarrhœa excepted), 278; Bright's disease, 183 deaths; suicide, 35 deaths; all other causes, 738 deaths.

The Medical Department of the Temple University, of Philadelphia, began its annual course of instruction on Thursday, October 1st. Dr. Matthew C. O'Brien has been appointed first assistant demonstrator of anatomy; Dr. Paul G. Weston has been appointed demonstrator of pathology and bacteriology; Dr. E. D. Reed has been appointed lecturer in practical pharmacology; Dr. Howard Reed has been appointed lecturer in orthopædic surgery; Dr. William D. Lithgow has been appointed instructor in materia medica; Dr. Daniel J. Donnelly has been appointed instructor in materia medica; Dr. Daniel J. Kennedy has been appointed instructor in physiology; Dr. Samuel Gerhard has been appointed instructor in symptomatology and physical diagnosis: Dr. Charles S. Barnes has been appointed demonstrator of obstetrics; and Dr. Milton E. Percival has been appointed instructor in surgery. The class in the depart-

Announcement of Prizes Awarded to the 1908 Graduates of the Medical Department of the University of Pennsylvania.—The alumni medal, which is given to the number of the graduating class who attains the high est general average in examination, was awarded to James Harold Austin. The Spencer Morris prize, consisting of the annual income derived from the investment of \$10,000, awarded each year to the member of the graduating class who passes the best examination for the degree of Doctor of Medicine, was awarded to Oliver Hazard Perry Pepper. The prize of an obstetrical forceps, which is given by the professor of obstetrics to the student furnishing the best report of a case of obstetrics occurring in the Maternity Hospital of the university, was awarded to Leo Fabian Bradley. The prize of an antiscptic minor operating case, offered by the clinical professor of orthopædic surgery for the best practical work in orthopædic surgery, for the best report of his clinic, or for an acceptable design in apparatus, was awarded to Gordon Joel Saxon, with honorable mention of Morris Cornfield. The Frederick A. Packard mention of Morris Cornierd. The Freuerics As Lackaus prize of \$100 given to the graduate who has proved himself to be the most proficient in the course of clinical medicine, was awarded to John Albert Kolmer. The surgicular prior of \$75 countried for the best essent prior of \$75 countried for the prior of \$75 countried for the prior of \$75 countried for the prior of \$75 countried for \$75 countrie based upon the results of original investigation in surgical anatomy, surgical pathology, or surgical physiology, was

The National Association for the Study of Epilepsy and the Care and Treatment of Epileptics.—The eighth annual meeting of this association will be held in Indianapolis, Ind., on Tuesday and Wednesday, November 10th and 11th. The meeting will be called to order on Tuesday at 10 a. m. by the president of the association, Dr. Henry M. Weeke and editors of the association, Dr. Henry M. Weeks, and addresses of welcome will be made by the Hon. J. Frank Hanley, Governor of the State, the Mayor of Indianapolis, the president of the Indiana State Medical Association, and others. The usual responses will be made and the annual address of the president will be delivered. The afternoon will be spent at the Central Indiana Hospital for the Insane, where Dr. A. E. Sterne will hold a clinic. Tuesday evening and Wednesday morning will be devoted to the presentation and discussion of papers. The officers of the association are: President, Dr. H. M. Weeks, of Skillman, N. J.; first vice president, Dr. W. F. Drewry, of Petersburg, Va.; second vice-president, Dr. T. C. Fitz-simmons, of Wilkesbarre, Pa.; secretary and treasurer, Dr. J. F. Munson, of Sonyea, N. Y.

The Health of the Canal Zone.-During the month of August there were 247 deaths in the Canal Zone, in a population of 123,391, corresponding to an annual death rate of 26.65 in 1,000 of population. There were 3 deaths from typhoid fever, 22 from æstivoautumnal malaria, 13 from clintophion fever, 2 from assistant analysis, 3 from hamoglo-binuric fever, 1 from whooping cough, 2 from diphtheria and croup, 2 from amebic dysentery, 7 from clinical dys-entery, 1 from beriberi, 2 from purulent infection and septicemia, 30 from tuberculosis of the lungs, 2 from other forms of tuberculosis, 3 from syphilis, 2 from cancer, 3 from chlorosis, 2 from acute rheumatism and chorea, from alcoholism, 6 from tetanus, 5 from bronchopneu-monia, 11 from lobar pneumonia, 5 from diarrhœa and en-teritis, under two years of age, 16 from chronic diarrhœa and enteritis, under two years of age, 2 from uncinariasis, I from puerperal septicemia. In the letter of transmittal accompanying the report Dr. Gorgas calls attention to the fact that during the past three years the death rate among the negro employees of the canal commission has dropped from 71.60 in 1,000 to 12.14 in 1,000. A comparison of total mortality for the past four years among the employees of the canal commission, both black and white, shows the following results: In 1905 the annual death rate in 1,000 of population was 35.93; in 1906, 62.12; in 1907, 27.59; and in 1908, 11.39. The showing in the general returns among the employees is equalled in all the special returns. The death rate of the Canal Zone is kept up to its high level by the deaths among the native population

An Ophthalmological Clinic for School Children.-An ophthalmological division in the Philadelphia Bureau of opntnalmological division in the Philadelphia Bureau of Health was established some months ago, with a central clinic in connection therewith, to which all school children were referred by the medical inspectors of schools. It is said that this clinic is the first of its kind in the United States. The establishment of this ophthalmological divisions of the contract of the contrac sion, with a separate clinic for school work, was the result of an examination in the summer of 1907 of a large number of school children, which showed that sixty per cent. had either eye strain or defective vision, 25 per cent. had cases being serious. The medical inspectors of schools in the course of their routine work have always given attention to eye defects, and in some cases have corrected these defects, referring other children to general clinics and dispensaries. In 1907 the cases of defective vision numbered 12,226, of which 3,179 were corrected and supplied with glasses. The new ophthalmological division was organized for active service on January 1, 1908, and is being largely increased. Dr. L. C. Wessels, chief of the division, has just submitted a report of the first three months' service, in which he states that during this time the total number of visits to the office was 1,267, and the total number of visits to the office was 1,207, and the total number of glasses prescribed free to children too poor to buy them was 345. Many of the children who were supplied with glasses had been classed as backward or supplied with glasses had been classed as backwards mentally deficient, when they could not see the blackboards nor the print in their books. The correction of these defects by the fitting of proper glasses was marked by a great improvement in both work and conduct. Many cases of inflammatory diseases were treated, among which were trachema and other contagious eve diseases, and these children were excluded from school until cured.

I. The Principles Underlying the Treatment of Acute Intestinal Obstruction. A Study of One Hundred and Twenty-one Cases of Acute Intestinal Obstruction from the Massachusetts General Hospital Clinic, By CHARLES L. SCUDDER.

2. The Desirability of Instruction in Psychopathology in Our Medical Schools and Its Introduction at Tufts,

By Morton Prince.

1. Treatment of Acute Intestinal Obstruction. -Scudder has the following to sav about the treatment of acute intestinal obstruction: The important and startling clinical fact in cases of intestinal obstruction is the profound intoxication, the toxemia, the general sepsis. The cause of this toxemia is an acute infection from the damaged gut. These two fundamental conceptions must underlie and be the basis of every thought and every effort in the treatment of intestinal obstruction. The changes in the bowel are so rapid that, the diagnosis having been made, action should be immediate. Delay may mean death. If there is doubt about the diagnosis, and the patient has abdominal pain without involuntary muscle spasm, is distended without a rise of temperature, cathartics should not be given. If there is a beginning peritonitis it will be increased by the catharsis. If there is infection in any part of the abdomen the increased peristalsis occasioned by the cathartic will spread the infection to another part of the abdomen. More harm is caused by the common practice of administering cathartics in the case of abdominal pain in which the diagnosis is uncertain than in almost any other way. No massage should be given to the abdomen for fear of causing a perforation or of spreading the infection. The patient should be kept in bed and quiet. No food should be administered by mouth for fear of causing intestinal peristalsis and thus increasing the peritonitis. No water should be allowed to be swallowed. Very little water is absorbed directly from the stomach. The swallowing of water increases peristalsis. No morphine should be given until operation is decided upon or the diagnosis is made, for morphine will conceal symptoms. If there is vomiting the stomach should be washed out with Early diagnosis permits early opwarm water. The author then describes the operative relief. eration, as performed by him, and the postoperative treatment.

 Gas Cysts of the Intestine.—Finney reports such a case. He reviews the literature and remarks that, in general, the ideas as to the ætiology of this peculiar affection may be grouped under three headings: 1, That it is a new growth; 2, that it is of bacterial origin; 3, that the presence of the gas cysts is due entirely to mechanical causes. From his own case he thinks that the most rational explanation of the growth would seem to be that it is a definite entity, a distinct variety of tumor, the cells of which have the faculty of secreting gas. Of the pathology of the condition, one cannot speak very definitely, remarks the author. The histological findings, however, reported by different observers have presented a strikingly uniform picture. The main characteristics have been a more or less dense fibrous tissue framework, containing many round and spindle cells in various stages of development. In this fibrous tissue mass are to be seen clefts and spaces of varying sizes. These are not uniformly lined with endothelium, but here and there in their walls most observers have reported finding peculiar large giant cells containing many nuclei; as many as fifty to sixty have been reported. In and about these giant cells air spaces have been almost invariably found. Here and there also an apparently definite endothelial lining to the walls of the air cysts has been observed. These tumors, as a rule, are richly supplied with bloodvessels, and some observers have reported the presence of hæmorrhages into the tissue. This was quite pronounced in his case. Smooth muscle fibre and elastic tissue have also been reported as present in some cases. Analysis made of the air in the cysts shows it to resemble very closely atmospheric air. The tumor has been observed in all the layers of the intestinal walls. In the majority of instances, perhaps, it is more pronounced in the subserous tissue.

2, 3. Gonorrhæa in Children.—Churchill and Soper state that the inoculation treatment of vulvovaginitis apparently shortens the stay of patients in Whether or not it actually lessens the hospital. total duration of the disease, as compared with other methods of treatment, future investigations must determine. Old stains are more effective than fresh ones. It is desirable, though apparently not absolutely necessary, to take the index while pursuing the treatment. There is no correspondence between the index and the vaginal discharge,-Butler and Long think that in the treatment of gonorrhœa in female children, gonococcus vaccine is more effective than local applications, which in some instances will delay recovery. The vaccine treatment is not only effective, but in many cases, more particularly those of some standing, produces very rapid improvement, and often recovery. This does not, however, hold good in all chronic cases. nor in all acute cases, many of which require a prolonged course of inoculations. This latter point should be held in mind by those undertaking this The most effective dosage of vaccine varies for different cases and at different times for the same case. This will be best determined by the patient's opsonic index to gonococcus. They have found doses varying from 5 to 50 million very satisfactory. Where inoculations are practised without the index in the quantities mentioned, they should be given every fifth or sixth day. Doses up to a hundred million may be used without causing any general reaction on the part of the patient, except in rare cases. The larger doses do not seem to have been more effective on the immunity wave or clinical condition, than smaller doses. There seems to be no particular advantage in a vaccine made from several strains of gonococcus over that made from a single strain. Their experience with the serum treatment in gonorrhœa in female children does not warrant recommending it in such cases.

5. Character of the Stools in Diarrhœal Affections of Infants.-Knox says that mucus is evident to the naked eye in a large percentage of diarrhœal stools of infancy. Its absence renders the presence of serious intestinal lesion improbable. Mucus in large amounts may be found in the stools in all intestinal disorders, but the proportion of cases with extensive intestinal alteration is greater when the quantity of mucus is in considerable excess. The appearance of blood suggests an alteration of the intestinal mucosa in proportion to the amount of blood present. On the other hand, extensive changes may occur in the bowel wall without the macroscopic presence of blood in the discharges. In like manner the presence of pus indicates, according to its quantity, alteration in the mucosa, particularly in that of the large bowel. The failure, however, to detect pus in the stools with the naked eye does not preclude the possibility of extensive intestinal lesion. Blood and pus are more frequently found in the middle half of infancy, and these elements at this time form a correspondingly more reliable index of the conditions of intestinal mucosa, while blood and pus rarely appear before the beginning of the second week of their illness. They are more frequently found from the third to the sixth or eighth week, and are usually absent af-ter this period, when the illness, if it continues, may assume a marantic character. Blood and pus are often found mingled in the same stool. Less often blood appears alone, and still less frequently is pus noted in the dejecta of infants who have not passed blood. The presence of these elements indicates the probability of thickening and infiltration or of ulceration of the mucosa of the small, but more certainly of the large intestine.

7. Appendicular Inflammation Complicating Pregnancy.—Babler remarks that perforative appendicular inflammation is one of the gravest complications of pregnancy; it complicates pregnancy with greater frequency than the tabulated cases would indicate. Pregnancy does not seem to predispose to primary appendicular inflammation. may precipitate an attack in certain chronic cases, but the clinical manifestations do not differ from those of appendicular inflammation in the nonpregnant. Before a diagnosis is made, the medical attendant must bear in mind the possibility of ureteritis and pyclitis. The diagnosis is not, as a rule, difficult. Of 235 cases of appendicular inflammation complicating pregnancy and the puerperium, 103 of the 207 cases complicating pregnancy were

of the perforative variety. Of these perforative cases, eighty-nine patients were operated upon; thirty-three aborted before, and thirty-seven after operation; thirty-six mothers died. All of the fourteen patients who were not operated upon in perforative cases died; nine infants died. Of the 104 nonperforative cases, fifty patients were operated upon; seven aborted, and one mother died. Of the nonperforative, nonoperated cases, six patients aborted and four died. Of the twenty-eight cases occurring during the puerperium eighteen were perforative. Of these latter, twelve patients were op-erated upon; four died. Two of the five not operated upon recovered; the abscess ruptured into the rectum. All of the patients in the nonperforative cases recovered. The mortality of appendicular inflammation complicating pregnancy is the mortality of delay. Early, efficient surgical intervention is the secret of success in the treatment of this disease. It is far better to evacuate an appendicular abscess before emptying the uterus, since such a procedure would eliminate the possibility of flooding the free peritoneal cavity with pus. If general peritonitis is present at time of consultation, accouchement force, followed by abdominal section, is indicated in the cases near the end of gestation. Cases have been reported in which general peritonitis was present at the time of operation, and yet the patient went to term.

9, 10. Serum Treatment of Cerebrospinal Meningitis.-Ladd has no doubt as regards the wonderful efficacy of Dr. Flexner's serum in the treatment of epidemic cerebrospinal meningitis, provided it is used on patients not moribund or on those in whom chronic hydrocephalus has not already developed. He confidently believes that statistical reports excluding these cases will show that our percentage of recovery will contrast favorably with our previously high percentage of deaths.—Sladen thinks that all cases of meningitis in which meningococcus infection is suspected should undergo lumbar puncture and serum injection as early as possible. The serum does no harm in cases not of the meningococcal type. It may do good. The course of the disease is changed by the serum. The long drawn out chronic cases are not seen, and the terrible sequelæ-often worse than death-are rare. As to the character of the serum, the rapidity with which signs and symptoms disappear, suggests an antitoxic property; the positive chemotaxis for polymorphonuclear leucocytes, and the promoted phagocytosis are most definite and constant features; finally, the reduction in the number of diplococci, the change in their staining properties, and the loss of viability speak for a bactericidal power -although it is a question if this may not be explained by the phagocytosis.

MEDICAL RECORD.

October 17, 1908.

 The Diagnosis of Peptic Ulcer, By Dubley Roberts.
 The Rational Treatment of Splanchnoptosis: Displacement of Viscera, Both Abdominal and Thoracic, By J. Manison Taylor.

. The Personal Factor in Disease,
By Beverley Robinson,

Abscess of the Lung from Ascending Infection from Appendicitis, with Report of Cases, By J. N. Hall.

Gonorrhoal Septichæmia, with Marked Cardiac Involvement, By JOHN D. THOMAS.

Vessel Anastomosis by Means of Rubber Tubing,
By Wilbur Ward.

2. The Rational Treatment of Splanchnoptosis. - Taylor observes that the causes of splanchnoptosis, movable, displaced, prolapsed, wandering, or dislocated hollow organs, lie far back in the origins of growth and development. A neurasthenic tendency is the fountain source of all such Some of these may be characterized as hereditary and others as acquired, but they are often so interwoven by evolution as to be ætiologically indistinguishable. Clinically it is important to estimate how much is referable to accident or constitutional weaknesses from whatsoever source. A large part of those factors which are blamed for the initiation of the splanchnoptosis, such as digestive faults, intestinal putrefactions, functional derangements, errors during parturition, and the like, are usually, if not always, merely efficient or instrumental, not primary causes. It is obvious, then, that the clinician must direct his remedial measures to the correction of the primitive defects, local or constitutional. By this course alone is it possible to achieve satisfactory repair. To relegate these extremely prevalent, insidious, often most baffling but ultimately disabling disorders to the operating surgeon and be content with whatever perfection of mechanical replacement he can accomplish, is to fulfill but a small part of our intelligent duty. Whatever the sources of causation, and they are necessarily various, differing in degrees and directions of evolution, we have then to overcome cellular vitiation in several situations, among which are loss of nutritive vigor in the vasomotor subcentres in the cord, through which the affected parts are innervated and, consequently, impairment of nutrition in the internal structures which contribute to support; and relative weakness in the external abdominal muscles. There are also contributory sources of weakness to be corrected, such as loss of tone in the skeletal structures, vitiation of motor innervations, and in the whole cycle of the autoprotective powers, oxygenation, etc. the difficult problems in relieving the splanchnoptoses is to secure suitable support for the relaxed abdominal walls. At best all artificial devices are but temporary measures, secondary to the radical restoration of the power of the tissues to perform their own duty, and they should be modified or abandoned when possible. The author then speaks of Morris Longstreth's belt, which, in his experience, avoids most evils and supplies the right kind of help. So far as the correction of the splanchnoptosis is concerned we have to deal with depleted nutrition of the whole organism, but particularly in the parenchyma of the abdominal organs, along with pronounced impairment of functional activities, which act as secondary causes of distensions, dilatations, obstructions to local circulation, and these in many ways retroact also upon the supporting structures. Much of the disability is due to vascular stasis, waterlogging, the effects of retained toxines and toxic wastes on circulation and there-

by constricting bloodyessels unduly. The object to be attained is to activate the total circulation both directly and generally. While many of our reliable drugs accomplish this in part, alone they often fail, whereas it will become obvious to any one, even to the scoffer, that manual treatment can and does rapidly and efficaciously improve circulatory activity, hence nutrition.

4. Abscess of the Lung from Ascending Infection from Appendicular Inflammation.—Hall reports fourteen such cases. He thinks that abscess of the lung is not infrequent in neglected cases of appendicular inflammation, and that a cavity may remain for a long time after the abscess has emptied through a bronchus. The absence of the usual color of the pus of amœbic abscess of the liver, of the history of dysentery, and the presence often of a definite colon bacillus odor to the expectoration lead us to think of the appendicular origin of the trou-The attack of appendicular inflammation may have been unrecognized, but questioning will establish a plain history in many cases. The bowing of the patient with concavity toward the right is not at all pathognomonic of lung involvement, either appendicular or amœbic, since he has seen it occasionally when dense adhesions had formed about an opened appendicular abscess, and in other diseases of the right side of the abdomen. The position assumed reminds one of that in certain chronic cases of sciatica. The prognosis is grave in cases of pulmonary involvement. Operation should be carefully considered. The chances of recovery must be doubtful at best, and we may accomplish much more by striving to avoid the complication than by attempting its cure. Although in any case we may have hepatic and pulmonary complications, in most cases they result from disregard of the early indications for operative intervention.

Gonorrhœal Septichæmia. — Thomas remarks that the treatment of these cases, as of all cases of ulcerative endocarditis, is very unsatisfactory. In the majority we can only use palliative measures and keep up the strength of the patient. In those cases where there is a mixed infection of streptococcus, antistreptococcic serum may be used. This has been used in some cases of malignant endocarditis where streptococci were shown to be present in the blood stream during life, with a few cases of recovery. If, as is held by some, the cases are pure streptococcic infection, which infection has gained entrance through the lesion in the urethra caused by the gonorrhoeal inflammation, and the gonococci or their toxines are not active agents in the infected blood or system, then the use of antistreptococcic serum, if it is any good at all, would be indicated. There have been some patients with infections, both by streptococci and staphylococci, who have been exceedingly benefited by antistreptococcic and antistaphylococcic serum. Some patients have been reported cured.

 19. Surgical Statistics: A Plea for a Uniform Registration of Operation Results, By E. W. H. GROVES.
- 2. Wertheim's Operation for Cancer of the Cervix.—Berkeley and Bonney state that the aim of Wertheim's radical abdominal operation for carcinoma of the cervix is to remove the uterus and annexa, with the diseased cervix enclosed in the upper part of the vagina, across which clamp forceps have been applied so as to prevent the escape of detached cancer cells into the normal tissues which have been exposed during the operation, and to excise together with these parts as much of the parametric and paravaginal cellular tissue and as many of the pelvic lymph glands as may be feasible. The writers dwell upon certain points of the operation, and give a summary of eighteen cases in which it was performed. Of these, fifteen resulted in recovery. In the three fatal cases death was due to shock.
- 3. Oxygen and Exercise.—Hill, from observations made on athletes, on himself, and on horses, has come to the conclusion that oxygen inhalation followed by, or accompanying, exercise is a most active and effectual form of treatment. In one case the increase in work done under oxygen was one sixth. Its influence is very great on the untrained or fatigued man. It enables a man to increase very materially the metabolism of his body. It should be, therefore, of value in the treatment of people fat and scant of breath, and those who overeat and take too little exercise, and in cases of emphysema and heart disease treated by graduated exercise. Possibly it may find a use in tropical climates to make exercise easier, and in men exhausted by the day's mental work and worry and who want a spin

on their bicycles to make the blood circulate and the appetite good.

18. Cancer Infection during Operation.-Ryall holds that from a surgical point of view cancer is a spreading infective process, not unlike other infective processes; that the cancer cell within the body is possessed of independent existence; that it contains the elements of infection, and that it can give rise to fresh cancerous outbreak in any part of the body whither it is carried by the lymph or blood stream, just in the same way as wandering bacteria are capable of forming secondary infective foci. In the treatment of cancer we have an infective process to deal with, and the question of cancer infection must be seriously considered. Cancer infection is the implantation of cancer cells from cancerous growths into tissues unaffected with the disease, and the occurrence therefrom of a fresh cancerous outbreak. Contact infection is the outbreak of fresh cancerous growth in healthy tissues which have been in contact with infected tissues. It is most frequently seen in the peritonæum, but is also found in other parts, such as the pleura, vulva, lip, and bladder. Distant implantation is the development of cancerous growths in parts distant from the primary growth, as the result of cancer cells being conveyed and implanted there. This form is also most commonly met with in the peritonæum. Suture scar infection following operation for cancer is a very common occurrence. It is the result of cancer cells being implanted by an infected needle or suture. Infection of the entire suture track is most frequently met with in abdominal cancer. Nodular infection of the wound is also fairly common. Diffuse or brawny infection of the wound is the most distressing form of wound infection. It is due to widespread dissemination of cancer cells at the time of operation. It almost invariably appears early, and is characterized by brawny infiltration of the tissues around the field of operation. In dealing with a cancerous growth, in which an exploratory incision has been made, the safest plan is to suture the incision and wait until healing has taken place before carrying out its removal. Unfortunately immediate removal is usually necessary. In such case the exploratory incision should be securely closed after checking all hæmorrhage; all instruments, sponges, sutures, towels, lotions, and lotion bowls used up to this stage should either be discarded or resterilized. After closing the wound, the skin in the neighborhood of the exploratory incision should be carefully washed and sterilized, and the hands of the surgeon and his assistants should be rewashed and cleansed with the minutest detail. It is well to place a pad of gauze in the exploration wound before closing it; this checks the leaking of blood and serum. As long as cancer cells are pent up we are operating under the best conditions, and therefore the infected tissues should always be removed en masse. Roughness of manipulation is accountable for many cases of cancer infection; this is especially true of operations for the extirpation of cancerous glands of the nećk, and of vaginal hysterectomy. The curette often opens uninfected tissues and implants them with cancer cells; hence it should be sparingly used.

The Treatment of Inoperable Cancer. By H. Morris.

On Pregnancy, Parturition, and the Puerperium after Ventrifixation (Hysteropexis Hypogastria),

By Sir W. J. Sinclair.

4. Cancer of the Colon: A Study of Seventy-two Cases,
By H. S. Clogg.

2. Inoperable Cancer.—Morris uses the term "cancer" in a general sense to include all forms of malignant new growths, embracing therefore rodent ulcer, sarcoma, lymphosarcoma, and endothelioma, as well as epithelioma and other varieties of carcias well as epithelioma and other varieties of carcinoma. The term "inoperable" means that the disease cannot be entirely eradicated, or permanent immunity hoped for, by a cutting operation, or by the actual cautery, or any escharotic aiding the knife. It does not imply that malignant disease is of constitutional as distinct from local origin and that as such it is ineradicable. On the contrary, cancer is at first, and so far as rodent ulcer is concerned throughout, a local disease. Even on this view there are four groups of inoperable cases, as follows: (1) Primary cancer affecting inaccessible parts and organs; (2) primary cancer which, though originating in an accessible part or organ of the body, has been allowed to extend beyond the limits within which an operation is prudent and complete removal possible; (3) certain cases of acute diffuse carcinoma and very rapidly growing or widely infiltrating new growths of exceptionally virulent character; and (4) recurrent cancer, where the disease has recurred in multiple metastatic foci or in parts beyond the limits of removal. The term "treatment" as applied to inoperable cancer means one of two things: (1) The employment of remedies and methods other than the knife to cure, ameliorate, or retard the disease, as well as to prevent relapses after its removal; or (2) the employment of the knife to give relief from pain, to prolong life, to restore function, and otherwise to make the patient's condition more tolerable. In cancer of the tongue the division of the lingual gustatory nerve gives the most signal relief from the pain, often otherwise intractable, which is referred to the side of the tongue, and indeed to the whole area of the distribution of the third division of the fifth nerve. Ligation of both lingual or both external carotid arteries causes a subsidence of cedema and salivation. Extraction of the teeth often gives great relief in these cases. It is sometimes not only justifiable but advisable to excise the greater part or even the whole of the tongue, even though the whole of the disease cannot thereby be removed. As regards cancer of the larynx, the writer personally is strongly opposed to the operation of total laryngectomy. When the patient refuses the operation, or when the disease and the general condition of the patient do not permit of its being undertaken, palliative means may give relief. Much improvement often follows tracheotomy when undertaken in good time. Whenever difficult respiration is threatened, tracheotomy should be done without delay, the trachea being always opened low down and as far from the growth as possible. Gastrostomy is probably performed too frequently in cancer of the œsophagus, and the use of a tube, short or long, should be resorted to more frequently. The results of the operation are unsatisfactory; in most cases, the improvement is of very brief duration. The very cases in which the stoppage of the efforts to swallow is most essential are the most unfavorable ones, as they invariably prove fatal soon after the operation from perforation into the air passages. In cancer of the stomach it is very doubtful if sufficient benefit is derived from gastrojejunostomy or other short circuiting operations to make it worth while undergoing them. For conditions other than cancer gastrojejunostomy is often of the highest value, but in cancer the prolongation of life is very limited, the ultimate sufferings are most severe, and the substitute functions are often unsatisfactory. The immediate mortality of the operation is probably not far short of forty-five per cent. Other complications which the operation does not prevent, if it does not assist in promoting, are the breaking down of the growth, hæmorrhages from the growth or from a recently formed jejunal ulcer, toxæmia, pulmonary infarcts, etc. The operation should not be proposed when cachexia and emaciation are very pronounced, when patients are seen very late, or when the growth does not cause stasis or obstruction of the pylorus. Somewhat more than seventyfour per cent. of patients with cancer of the rectum either see the surgeon too late or else have the disease in such a position that cure by operation is impossible. Colotomy, besides entirely obviating the risk of death from intestinal obstruction, affords relief from many of the usual symptoms of rectal cancer and retards the rate of increase of the growth. The prospects from colotomy are better when the operation is done before complete obstruction sets in. As substitute operations for colotomy when the disease is near the anus, linear proctotomy and erasion of the growth have sometimes proved to be temporarily beneficial. As regards cancers of the uterus, the percentage of inoperable cases has steadily lessened, Wertheim's method being largely responsible for this improvement. In certain cases of cancer of the breast, the breast should be removed for palliative purposes, even when there is widespread glandular infection. No operative treatment can relieve that terrible condition known as cancer en cuirasse. The writer has little of recommendation to say as regards the various treatments by thyreoid feeding, by injections of soap, by Doyen's vaccine or the different sera or killed cultures, by electric currents of high voltage and high frequency, or by the mixed toxines of the streptococcus of erysipelas and the bacillus prodigiosus (Coley's fluid). He discusses the trypsin treatment very fairly and thoroughly, and decides against it. The local atrophy and degeneration of a cancerous growth induced by subcutaneous injections of trypsin in the neighborhood of a tumor or into the tumor itself cannot be accepted as evidence of the successful treatment of cancer. Further, direct injection into the tumor or into its periphery always causes an extreme amount of physical suffering. Pancreatin applied locally does have a beneficial effect in removing all dead and septic tissue, and in obtaining a clean, nonseptic surface.

 The Hæmoglobinuric Malarial Fever of Teneriffe. Its Treatment with Voa-Fotsy, By FONTOYNONT. By Pierre Cruet. Articular Hæmophilia,

2. Articular Hæmophilia.—Cruet divides hæmophilic diseases of the joints into two classes, the spontaneous and those caused by a violent effort. The spontaneous is the only true form of hæmophilic joint disease; in the other the joint manifestations may be present in normal individuals, but greatly aggravated when the hæmorrhagic diathesis is present. The spontaneous arthrites he divides into slight hæmarthrosis, benign painless hæmarthrosis, serious painful hæmarthrosis, and chronic recurrent hæmarthrosis. The spontaneous differs from the other form: I, In the cause, in the spontaneous appearance, without any, or only a slight, traumatism, or a long walk, in the other following a serious injury. 2, In the time of its appearance, coming on slowly, five or six hours after the walk or slight effort in the former, immediately in the latter. 3, In the acuteness of the symptoms, which is moderate in intensity in the spontaneous, but considerable in the other form. 4, In the duration of the acute period, which is generally about eight days, rarely more than fifteen, in the spontaneous, and from fifteen to eighteen in the traumatic. 5, In the course and result, restitutio ad integrum being the rule in the spontaneous cases, except in the chronic form, while pseudoankylosis is apt to persist in the traumatic cases.

- Contribution to the Diseases of the Conus Medullaris, By RABINOWITSCH.
- Remarks on Resection of the Elbow Joint with Preservation of its Mobility, By W. Lossen.
- I. Acute Ectasia of the Stomach.-Borchardt says that, although the various names under which this disease is known, such as acute ectasia of the stomach, mesenterial occlusion of the intestine, arteriomesenterial occlusion of the intestine, duodenal ileus, and angular occlusion of the duodenum. may be justified from a pathological standpoint, still clinically the condition is one of occlusion of the duodenum, with all the consequences of occlusion high up in the intestine. In his opinion acute atony and ectasia of the stomach is the primary trouble in the majority of cases. It produces occlusion of the duodenum by pressing the intestine before it into the true pelvis, rendering the mesentery tense, while, as the accumulation of fluid in the stomach increases, the occlusion grows firmer and firmer, movement of the intestine becomes impossible, and the occlusion becomes irremediable without artificial help. The diagnosis of this condition is easy as a rule if one thinks of its possibility. And it should be thought of in every case where, after narcosis, operations of any kind, particularly after laparotomies and especially after operations on the biliary passages, or during convalescence from severe diseases, or after errors of diet, or after severe vomiting, serious abdominal symptoms put in an appearance. Our endeavor should be not to choose the right operation, but to render any surgical intervention unnecessary by an early diagnosis.
- 2. Meningitis Serosa Spinalis.- Mendel and Adler report a case of this nature which was successfully operated on by laminectomy of some of the dorsal vertebræ and evacuation of one and a half teaspoonfuls of clear liquid, which was unfortunately

5. Europhen. - Meissner speaks highly of europhen as a cleansing, analgesic, and odorless powder for use in the treatment of venereal ulcers.

6. Adrenalin Glycosuria and the Influence Exerted upon it by the Extract and the Juice of the Pancreas.-Frugoni arrives at the following conclusions from his experiments on animals: 1, A quantity of adrenalin sufficient to produce glycosuria will fail to do so when given an animal in an injection which contains a sufficient quantity of extract of the pancreas. 2, The pancreas juice has also the power to prevent adrenalin glycosuria when it is injected in large quantity before the adrenalin; a certain amount of time is necessary for its, at least partial, absorption. The best results were obtained when it was introduced through the peritonæum two hours before the subcutaneous injection of the adrenalin. 3, As the adrenalin is taken from an organism in which the circulation is overcharged with sodium bicarbonate, through the previous endovenous injection, it is probably modified in its chemical structure and its general biological action neutralized. 4, The juice of the pancreas in contact with adrenalin in

the test tube for from ten to fourteen hours is changed so that it loses its chemical reactions and its biological characteristics are fundamentally modified. 5, The same effects are produced when adrenalin is brought into conjunction with corresponding salts. 6, Finally, the pancreatic juice, when it has previously undergone dialysis, behaves toward adrenalin as an indifferent fluid.

7. Diseases of the Conus Medullaris .-- Rabinowitsch says that the clinical symptoms met with in these patients may be divided into three groups: I, Anæsthesia of the urethra and rectum; loss of the voluntary innervation of the bladder and rectum; impotence. 2, Anæsthesia of the genitals, of the perinæum, of the anococcygeal region, and of the neighboring portion of the nates. 3, Loss of the reflex of the right tendo Achillis.

MUNCHENER MEDIZINISCHE WOCHENSCHRIFT. September 1, 1908.

Some Observations on Experimental Anæmias, By Morawitz and Pratt. The Absolute Plethysmogramm,

By WOLFF-EISNER.

13. The Technique of the Extraction of Needles, By HOLZKNECHT and GRÜNFELD.

Experimental Anæmias. - Morawitz and Pratt conclude that in severe anæmias experimentally produced the oxidations in the tissues are not carried out completely to the final products of metabolism, but are brought to an end partly in the blood or in other organs. The true cause may therefore be lack of oxygen.

4. The Thymus in Exophthalmic Goître.—Capelle reports a case of removal of the thyreoid gland in exophthalmic goître, followed by death in twelve hours from a thymic condition. He believes that the presence of a large thymus is a contraindication

to operative intervention in this disease.

5. Periodic Acetonæmia of Large Children .-Hecker believes that the periodical acetonæmia of large children is not an accidental disturbance, but is a constitutional anomaly in the sense of an arrest of development and of the fat removing function.

Angioneurotic and Some Other Examples of Essential
Œdema in Children, By H. Schwarz.

1. An Experimental Study on Hæmorrhage Following Section of the Uterine and Ovarian Vessels in Dogs and Its Possible Bearing on Ruptured Gestation .- Robb made a series of thirtyone experiments, and believes, as a result, that the intraabdominal hæmorrhage which occurs in women collapsed after rupture of an ectopic gestation sac is not, in itself, sufficient to cause death in such Death is due rather to shock, which may be increased by various surgical procedures. If operation is performed immediately after the occurrence of the hæmorrhage the superadded shock is likely to be very dangerous. In the author's experiments the difference in resisting power between dogs and women was borne in mind, but the experiments were of so severe a nature that the probability of fatal hæmorrhage was as great or greater than that to which women are subjected when a tube is ruptured. The manipulation of the tissues in the latter case probably disturbs the clots which may have formed in the bleeding vessels, and a hæmorrhage which had ceased may thus be reawakened.

Ovariotomy during Pregnancy.—Cumston 5. has found it advisable to remove ovarian tumors five times in connection with pregnancy. The indication for operative interference would be furnished by the occurrence of severe symptoms, of whatever character, proceeding from the tumor. The author believes that the operation should always be performed in the presence of severe symptoms, especially such as may arise from twisting of the pedicle. The condition is not a common one, and there are doubtless instances in which the tumor causes no sypmtoms, and may not be discovered until after labor. In the majority of cases the presence of a cystoma does not add to the severity or the dangers of labor. It is thought that there may be greater tendency to postpartum hæmorrhage if such a growth is not removed prior to The growth should usually be removed by abdominal incision, although there are cases in which it is quite feasible to remove it by the vagina.

(Continued from page 765.)

COMBINED MEETINGS OF SECTIONS I AND VII.

Recent Developments in Regard to the Relations of Human and Bovine Tuberculosis .- Dr. NATHAN RAW, of Liverpool, England, said that Koch was right in his assertion that human tuberculosis was different from bovine tuberculosis; but that

he was in error when he said that boyine tuberculosis could not be transmitted to human subjects. During the last fifteen years he had had the opportunity of observing over 5,000 persons with tuberculosis, and of that number 3,000 had died in the hospital. Careful pathological examinations had been made in a very large number of the cases, and as a result of the studies made in these cases he was able to confirm the opinion, which he had advanced in 1903, that the tubercle bacillus was divisible into the typus humanus and the typus borinus. He believed that. on account of the fact that for centuries the human family had been feeding upon the products of tuberculous animals, the human system had become tolerant of bovine tubercle bacilli. Man was attacked by two distinct varieties of tuberculosis; one conveyed by infection from person to person, and the other transmitted by infected food products. Tubercle bacilli of the human type produced pulmonary tuberculosis, ulceration of the intestines, and tuberculous laryngitis. The bovine type of the bacillus produced tuberculous peritonitis, tuberculosis of the lymphatic nodes, acute miliary tuberculosis, tuberculous joints, tuberculous meningitis, and lupus. Clinically, these lesions were antagonistic to each other, so that a person who had been attacked by the human type of bacillus would not be attacked by the bovine type of the organism. In addition to the open air treatment of tuberculosis, tuberculin therapy was necessary to thoroughly eradicate the disease from the blood, and to produce an artificial immunity. Tuberculin R was of little value in the treatment of pulmonary tuberculosis, although it was of the greatest possible service in treating all infections of a bovine origin. This was what one should expect in view of the fact that it was produced from human tubercle bacilli. It acted by producing an immunity in those forms of tuberculosis. In the treatment of infections with the human type of the bacillus we needed a tuberculin prepared from bovine sources, and in his hands it had proved of great assistance, particularly in early cases. In all, he had treated about 200 cases of tuberculosis with tuberculins with encouraging results. He believed that pulmonary tuberculosis was the direct result of inhaling vitiated air containing tubercle bacilli, or, in some cases, by absorbing them through the alimentary tract. When tuberculosis was eradicated from dairy cows it would be a rare event to see a case of surgical tuberculosis.

The Susceptibility of Cattle to the Virus of Surgical Forms of Human Tuberculosis.—Dr. R. M. Dixwidden, of the Experiment Station in Arkansas, said that he had inoculated material derived from two cases of tuberculous lymph nodes of the neck, from one case of tuberculous arthritis of the knee, and from one case of genitourinary tuberculosis into yearling cattle by the intraperitoneal route. His results showed that this material was no more virulent for cattle than the sputum of consumptives. The theory that certain forms of surgical tuberculosis in man, especially those involving the lymph nodes, were due to bacilli of the bovine type received no support from these experiments.

Tuberculous Cervical Adenitis. A Study of the Tubercle Bacilli Cultivated from Fifteen Consective Cases.—Dr. Paul A. Lewis, of Boston, said that he had found tubercle bacilli of the bovine type

in fifteen cases of tuberculosis of the cervical lymph nodes. The studies were made on seventeen cases of primary tuberculosis of the cervical lymph nodes. In two cases there was no growth; in the fifteen others tubercle bacilli were found. Nine of the cultures were virulent for rabbits, and three of these were also virulent for calves. There were six non-virulent cultures. These, after having been transferred to glycerin agar and glycerin bouillon, grew rapidly. One of them gave an alkaline reaction, and the five others gave acid reactions.

Studies of Tubercle Bacilli from the Tissues of Special Forms of Primary Cervical Adenitis in Man, with Particular Reference to Intermediate and Atypical Varieties of Bacilli.-Dr. CHARLES W. DUVAL, of Montreal, said that the material upon which his work had been based had been isolated from four cases of primary cervical adenitis in the human subject. The clinical picture was clear in each case, a fatal termination occurred in from six to eight weeks from the onset, and necropsies showed that the fatal termination had been due to acute general miliary tuberculosis. The organisms had been recovered directly from the cervical pus at the time of the surgical intervention. Of the four cultures studied, one corresponded to the bovine type of the bacillus, and another corresponded to the human type. The two other cultures were intermediate or atpyical forms. The author believed that one of them was perhaps of a modified bovine strain, while the other was perhaps of an avian type attenuated by its sojourn in man.

SECTION II.
(Continued from page 668.)

Diagnosis and Treatment of Early Cases of Tuberculosis.

Comparative Importance of Treatment in Sanatoria Near at Hand and an Entire Change of Climate.-Dr. Frederick I. Knight, of Boston, said that climate was a factor in all treatment of tuberculosis; we always had climate at our doors. Consequently, the sanatorium treatment and the climatic treatment could not be properly compared. He believed that sanatorium treatment was the best treatment in the early cases, because it served to educate the patient in the proper method of caring for himself. Sanatorium treatment near the home of the patient was much preferable to unrestrained life under radically changed climatic conditions. A radical change in meteorological conditions was sometimes necessary for its influence upon metabolism. The relative value of change of climate could only be determined by a careful comparison of the statistics of observations made under the same conditions in different parts of the world.

The Comparative Importance of Sanatoria and of Home and Climatic Treatment.—Dr. C. Theodore Williams, of London, said that sanatorium life was the model for the consumptive, because there he learned what to do and what to avoid. The conditions of the patient's life were regulated, and he had to do what he was told. Improvement occurred in spite of the patient and his tendencies toward bad habits. In consumption the only condition under which a patient could expect to get well was by obeying orders implicitly. The

sanatorium treatment was the best for the working classes, because they could not carry on the details of the routine in their own homes. For the wealthy classes open air treatment could be carried out at home; but even for patients in such a financial condition he would advise sanatorium treatment for three months or longer, for the educational benefit to be derived from it. He was of the opinion that climatic treatment was of decided advantage in the majority of cases, particularly to patients in the early stages of the disease.

The Comparative Value of Change of Climate and of Treatment in Sanatoria Near at Hand in Cases of Pulmonary Tuberculosis.—Dr. CARROLL E. Edson, of Denver, said that the essentials of the treatment of pulmonary tuberculosis were outdoor life, rest, abundant nutrition, sunshine, and prolonged medical supervision. It was absurd to speak of the climatic treatment as opposed by the sanatorium treatment, because climate, which was the sum total of the meteorological conditions prevailing in a given region over considerable periods of time, was always present. The essentials of treatment as outlined before showed that a climate might be selected in which the patient might have all these essentials in as large proportion as possible for the greater portion of the time. The physician should see whether the climatic conditions were as good at home as could be obtained in another part of the country or of the world. A change of climate should be made if it could be done consistently with the other conditions of right living. A change of climate only offered an opportunity to obtain a cure of the disease; the climate did not cure in itself.

The Diagnosis and Treatment of Early Cases of Tuberculosis.—Dr. LAWRENCE F. FLICK, of Philadelphia, said that tuberculosis was primarily a lymphatic process. Tuberculosis of the lungs, which was of most interest to the physician, was most frequent, next to lymphatic tuberculosis, and usually began at the apices of the lungs, along their posterior pleural borders. The disease localized itself more frequently on the right side than on the left side of the body. It was possible to make a diagnosis of pulmonary tuberculosis early, before there was much destruction of tissue, although it was not easy. It should be looked for, however, in all persons who had been exposed to contagion. The subjective symptoms of the first stage were cough, supersecretion of mucus, loss of appetite, malaise, and supersensitiveness of the nervous system. The objective symptoms were elevation of temperature, disturbance of the pulse rate, and dilated pupils. The physical signs were slight bronchovesicular breathing over the affected area, a pleuritic rubbing on expiration, increase in tactile fremitus and vocal resonance, slight bronchophony, and impairment of resonance. Tuberculosis was still early in time and prognosis so long as it was limited to one lobe of one lung, or even to two lobes, provided there was not much destruction of tissue. The symptoms in the more advanced stage were usually malaise, gastric disturbance, some sense of shortness of breath, a sense of physical incapacity, cough, expectoration, chilliness or a sense of heat, and loss of appetite. The physical signs were bronchial breathing, prolonged expiratory murmur, pleuritic rubbing, increase in tactile fremitus and vocal resonance, feeble bronchophony, and impairment of resonance. When the infiltration was dense or there was a secondary infection, the symptoms all became more marked, and there was dulness on percussion. When the process had gone on to cavity formation, and the cavity was small, tactile fremitus and vocal resonance would again become normal, branchophony would be replaced by whispering pectoriloquy, and the percussion note would become tympanitic. As a small cavity dried up, the physical signs again became nearly normal, except as to quantity. Absence or deficiency of normal physical signs should raise a question of tuberculosis. Absence of tubercle bacilli from the sputum should not weigh too heavily against the diagnosis. The treatment at home under proper medical supervision was as good as any treatment in the world. The treatment of pulmonary tuberculosis was not a question of climate, but a question of home life. Recovery he considered to be an arrest of tissue destruction and a return to normal physiological health. All that was necessary was a simple life, properly selected diet, fresh air, and such medication as was necessary to restore these physiological functions. It was not certain that a patient could ever become sterile after once having been infected with tubercle bacilli. In advanced cases the treatment must be more heroic; the patient should be put to bed at complete rest, then be kept at comparative rest, and finally be put on graduated exercises. A good general basis for the diet was one meal of solid food a day and three quarts of milk and six raw eggs a day. The one meal should consist of beefsteak, roast beef, or roast mutton, with fresh vegetables and fresh fruit. The patient should under no circumstances breathe air that had already been breathed. Draughts could do him no harm if he was properly clad. So far as drug treatment was concerned, he considered iodine to be the best drug. Other drugs should be used to stimulate physiological action, never to interfere with it. Home treatment was the best, as it prepared the patient for after life. When proper discipline could not be established at home, the patient should be treated in a sanatorium in the climate in which he had been accustomed to live. After sanatorium treatment had restored the patient to physical health, a course of home treatment should be instituted to teach him how to live in order to keep well.

Dr. Carl Wirth, of St. Paul, said that he agreed with Dr. Flick that home treatment was the best for tuberculous patients. He advocated a hypodermic method of medication, for which he alleged excellent results.

Dr. Vergara Lope, of Mexico City, said that in his opinion a great altitude gave the best conditions under which to treat patients with pulmonary tuberculosis. He thought that the psysiological changes went on better at a great altitude than at a lower level, and he maintained that the nearer normal the ordinary functions of the body were the better results would be obtained from treatment.

Dr. F. M. POTTENGER, of Monrovia, Cal., said that the essentials of all treatment in cases of tuber-culosis were to apply all the methods that might raise the resisting powers of the patient. Talk of climate was getting away from the pith of the mat-

ter. Ninety-five per cent. of the patients must get well at home or not at all. Tuberculosis was cured in all climates, and while he practised in a climatic resort, he honored those who were trying to accomplish results in the homes of their patients. One should make the best of conditions as they existed at home. Intelligent management was the basis of all treatment. The physician should school himself until he was able to make an early diagnosis. It must be borne in mind that tuberculosis had a period of latency of months and even years before marked symptoms developed.

Dr. WOODCOCK, of Leeds, England, said that the sanatorium frequently put the patient in good condition in three months, but that three months' treatment was feeble. The sanatorium treatment should be grafted on to the ordinary life of the patient under the supervision of the general practitioner, if results that would be lasting were to be obtained.

results that would be lasting were to be obtained.

The Use of the X Rays in Diagnosis.—Dr.
FRANCIS H. WILLIAMS, of Boston, said that the early diagnosis of pulmonary tuberculosis was the serious and important problem in the handling of patients. He was an advocate of the use of the x rays for the detection of the extent of the disease, for the diagnosis of acute miliary and fibroid tuberculosis, for tuberculosis associated with emphysema, pleurisy with effusion, pneumothorax, etc. for the recognition of cavities and enlarged tracheal glands, and for the exclusion of cases simulating tuberculosis. The x rays were most useful very early in the disease, as they would sometimes show the existence of a focus of disease that could not be detected by physical examination. They also gave information of the conditions in the deeper portions of the lungs, of the size of the heart, and of the action of the diaphragm. The x rays were difficult of application and of interpretation, but in the hands of an experienced operator they gave a considerable amount of information. He advised precautionary x ray examinations from time to time of persons who had been exposed to the disease.

Röntgenography in the Diagnosis of Early Tuberculosis of the Lungs.—Dr. Henry Hulst, of Grand Rapids, Mich., said that he preferred the fluoroscope to the photograph in the use of x rays in the diagnosis of tuberculosis. He used a low vacuum tube with short exposures, as such a combination gave the best details. In employing this method of diagnosis the tube must be carefully chosen, the eye of the observer must be trained, and the screen and the plate must also be carefully se-

lected.

Fluoroscopy as a Routine Clinical Method of Diagnosis.—Dr. EDWARD RIST, of Paris, said that fluoroscopy should be considered as a routine method applicable to the ordinary examinations of patients. The method he believed should be studied by the physician as much as stethoscopy. Fluoroscopy showed particularly the extent of the lesions and the existence of cavities. It gave valuable information in every case of tuberculosis of the lungs.

Dr. CHARLES L. MINOR, of Asheville, N. C., said that it was extremely important that the practitioner should make his own examinations, and that he should understand the meaning of the things that he saw, that fluoroscopy was a very important method

of examination, and the practitioner should become familiar with it. Nevertheless, he did not consider it a very early diagnostic method. He thought that physical diagnosis was better for the early establishment of lung involvement than the x rays.

Dr. von Leube, of Berlin, said that if the x rays gave negative evidence, the result might be used to give the patient a sense of security, but that the physician should never rest satisfied until by repeated examinations of all kinds he could prove the nonexistence of grounds for his suspicions. He considered percussion and auscultation to be more

valuable signs for steady dependence.

The Value of Hæmoptysis as an Early Symptom of Pulmonary Disease .- Dr. JAMES M. AN-DERS, of Philadelphia, said that in the acute forms of pulmonary tuberculosis hæmoptysis might be the first symptom in a case of acute tuberculous pneu-Hæmorrhage was also frequently seen in cases of acute tuberculous bronchopneumonia; but this form of tuberculous disease also occurred during the course of chronic pulmonary tuberculosis, and under such conditions was not, as a rule, ushered in by the expectoration of blood. In chronic ulcerative pulmonary tuberculosis and in fibroid phthisis hæmoptysis was also a frequent symptom. In the latter variety of tuberculous disease copious hæmorrhage was seen. In the cases of chronic ulcerative phthisis hæmorrhage rarely occurred except when the lesions were large enough to be made out by the physical examination of the patient or by the x rays. Cases of hæmoptysis in which all the clinical and laboratory findings were negative were to be regarded as of tuberculous nature until disproved by the tuberculin test or by some other positive method. Of course, hæmoptysis was not pathognomonic of pulmonary tuberculosis, but it was of exceptional importance as a cardinal symptom. The collective investigations of the writer embraced a total of 3,506 cases, in which 338 patients, or 9.6 per cent., had hæmorrhage at the very beginning of the disease. Generally speaking, the value of hæmoptysis as a symptom for diagnosis in early pulmonary tuberculosis must be quite considerable, with no tendency to magnify its importance

The High Altitude Treatment of Tuberculosis, with Special Reference to Febrile Conditions .-Dr. O. Amrein, of Arosa, Switzerland, said that any factor that helped one to benefit patients suffering from pulmonary tuberculosis must be accepted with enthusiasm. The best conditions for patients of this class were proper care and the best possible climate. High altitudes possessed the following poperties: Low barometic pressure, dry and pure air, abundance of sunshine and the greater actinic power of the sun's rays, and a great number of bright, clear days, even in winter. Treatment in such a climate resulted in an improved condition of the blood, increased vitality of the bodily functions, diminution of the cough and expectoration, and the disappearance of night sweats. The tendency to hæmorrhage was no contraindication to residence at an high altitude, except when the hæmorrhage was due to increased blood pressure. Fever patients improved at Arosa, as a rule, but when the pulse was 120 or more they did not do so well. Many bad

cases became stationary on account of the beneficial influence of the climate, and the patients were able to preserve their health and to do some work. The "sun cure," which had recently been introduced as a method of treating laryngeal tuberculosis, was more effectively carried out in the mountains than elsewhere. The specific sera could be given with more certain effects in the mountains than elsewhere. Of fifty-one patients in the first stage of pulmonary tuberculosis, with a temperature of 38.5° C. (101.3° F.), fifty-one, or 100 per cent., lost their fever at Arosa; of forty-seven patients in the second stage of the disease, with an equal amount of fever, forty-one, or 87.2 per cent., lost their fever; and of four patients in the third stage of the disease, three, or 75 per cent., lost their fever. Of nine patients in the first stage of pulmonary tuberculosis, with a temperature of over 38.5° C. (101.3° F.), six, or 66.6 per cent., lost their fever; of forty-seven patients in the second stage of the disease, thirty-seven, or 78.7 per cent., lost their fever; and of twenty-five in the third stage of the disease, twelve, or 48 per cent., lost their fever.

(To be continued.)

Wetters to the Editors.

AN EMBARRASSMENT TO BE AVOIDED.

NEW YORK, October 12, 1908.

To the Editors:

In view of the establishment of a female nurse corps in the United States Navy, may I be permitted as a layman to recount some of my experiences in a hospital last summer, when I was a patient suffering from malarial fever? It seemed to me while in the hospital that the female nurse was a distinct hindrance to recovery in that her presence checked some of the functions of the body most necessary to recovery. A comparison of my feelings, when I became convalescent, with those of other patients showed me that I was not alone in

my opinions.

In relieving the bladder or in a movement of the bowels I found that conditions of flatulency brought the excretory functioning in those cases within the cognizance of the young women on the other side of the screen placed around my bed. After that it seemed utterly impossible to make the necessary voiding. The excrementitious material would descend until there was danger of an explosion of flatulency, and then the sex considerations would intrude and the muscles would refuse to operate. They would contract, and no effort of my will could force any expulsion. I am not unnaturally modest, and have knocked about enough in this and foreign countries to be without any squeamishness in those matters. When I communicated my trouble to the orderly, he remarked cynically: "Why do you let that bother you? They're only nurses." Bravely did I try to apply this brutal philosophy to the urgency of my case, but it was ineffectual, and a catheter was used. I protested that it was not necessary, that it was the presence of the women nurses within sound that

kept the flow back, but it was impossible to influence the house doctor with any such argument. Finally, when the absence of any movement of the bowels was causing some concern, I told the orderly about 2 a. m. to get the nurse out of the ward and I would show him what was the matter. "Keep her out for half an hour if you can," I said. He did, and drew the screen around me. No sooner was I sure that she was out of hearing than the muscles were let loose and acted with beautiful freedom. The accumulations of wind which I had feared would manifest themselves were there, and for minutes the noise accompanying these excretory movements reverberated about the ward, but there being only men present, I did not care. The relief, of course, was immediate, and I began to mend. After that the orderly kindly arranged to get the nurse out. On reaching convalescence, I spoke to others about the unwillingness of the organs to work when young and pretty women were near, and several said: "Why, that is exactly how I felt about it." It occurred to me that it should be so arranged in the treatment of patients that the sex quesion should be entirely eliminated. The most important agents in recovery are the free movements of the bowels and the bladder, and if they are checked or retarded in any way, there is just so much danger added to the situation. It is idle to talk about this feeling of men patients being controllable by the will. It is not. Being a sex sentiment, it passes beyond the control of the will and becomes involuntary and instinctive.

There is no reason to think that sailors will be any less affected by the proximity of pretty young women nurses than I was, and therefore it is natural to conclude that the work of the excretory organs will be hindered, and perhaps in more than one case to a disastrons extent. There is a certain daintiness about women that is charming to have in a sick room, but is there not a corresponding inevitable interference with the normal functioning

of organs that should not be tolerated?

W. E. H.

** Our correspondent's embarrassment was natural, but it should be borne in mind that flatulence is one of the things concerning which a nurse is expected to report. The hospital people might have explained this to W. E. H. and the other patients. A tactful nurse will appear to absent herself on such an occasion as our correspondent mentions, but she will really remain within observing distance.

Book Notices.

[We publish full lists of books received, but we acknowledge no obligation to review them all. Nevertheless, so far as space permits, we review those in which we think our readers are likely to be interested.]

Angina Pectoris, Von Dr. Louis Peiser, Arzt am deutschen Hospital und deutschen Dispensary der Stadt New York. Stuttgart Ferdmand Enke, 1008. Pp. 100.

Dr. Peiser, of New York, has written a book for which he can be congratulated. It does not contain any new theories—that was not the author's intention, as he remarks in his introduction that he has as a general practitioner not the time for going

so deep into the subject-but what he says is a well

compiled résumé of our present knowledge of angina pectoris.

The book is well written in a simple, plain German, which will permit even a non-German who has a fair knowledge of the language to read the book with interest. The author begins with three short case histories, which he uses as examples to build up a general description of angina pectoris, its history, ætiology, and pathology. Here follow eleven more case histories as an introduction for the coming chapters, in which the author describes the clinical aspect and tendency of angina pectoris, autopsy findings, prognosis, diagnosis, distinctive diagnosis, therapeutics, and prophylaxis. The bibliography goes fully into the subject, and there are one hundred and thirty authors cited.

Every general practitioner will be thankful to the author for this clearly and concisely written book, which surely would find a very large circle of readers in America if it was translated into English.

The Harvey Lectures. Delivered under the Auspices of the Harvey Society of New York, 1906-1907. By Professor A. E. WRIGHT, Professor C. A. HERTER, Professor W. T. PORTER, Professor J. G. ADAMI, Dr. S. J. MELITZER, Professor F. G. BENEDICT, Professor E. B. WILSON, Professor F. G. MENDELLE, Professor F. G. WILSON, Professor F. WILSON, P fessor George S. Huntington, Professor W. T. Councilman, and Professor Friedrich Müller. Philadelphia and London: J. B. Lippincott Company, 1908. Pp. 314.

The appearance of the second volume of the Harvey Lectures shows no recession from the high standard set by the society in its first year. By affording the medical profession of New York and its vicinity the opportunity of listening each year to the latest results of research in important fields, presented by men qualified by their own work to speak with authority, the society is doing a real public service. Through the publication of these lectures it widens its audience to embrace all English speaking medical men in whom the routine of practice or the pursuit of its rewards has not been able to quench that thirst for true knowledge so characteristic of the profession as a whole.

That the society appreciates the special interest to practitioners of investigations that promise more immediate practical application to the cure of disease, this volume shows. It opens with a brilliant piece of special pleading for the recognition of the achievements of vaccine therapy, by Sir Almroth E Wright, its most prominent student; it closes with a judicial review of our present knowledge of the cardiac neuroses, their diagnosis and their treatment, by Germany's foremost clinical teacher, Professor Friedrich Müller.

Between these one finds illuminating discussions of the following wide range of subjects: The Common Bacteriological Infections of the Digestive Tract and the Intoxications Arising Therefrom, by Professor C. A. Herter, of Columbia University; Vasomotor Relations, by Professor W. T. Porter, of Harvard University; The Myelins and Potential Fluid Crystals of the Body, by Professor J. G. Adami, of McGill University; The Factors of Safety in Animal Structure and the Animal Economy, by Dr. S. J. Meltzer, of the Rockefeller Institute for Medical Research; Metabolism during Inanition, by Professor F. G. Benedict, of Wesleyan

University; Some Recent Studies of Heredity, by Professor E. B. Wilson, of Columbia University; and The Genetic Interpretation of the Variations in the Genitourinary Tract, by Professor George S.

Huntington, of Columbia University.

Of these, some, like Benedict's, make us marvel at the minute exactness with which the human body can be studied; others, like Porter's, lay bare the extent of our physiological ignorance, and give a rough jolt to our complacent satisfaction with crude clinical explanations of complex phenomena. Huntington sets before us an imposing array of anatomical facts; Meltzer, a fascinating physiological generalization. All alike show the scientific method at work. The reading of such a volume exerts an influence beyond that of the knowledge it conveys, and the lectures can be warmly recommended to every physician.

Public Health and Marine Hospital Service:

Official list of changes of stations and duties of commissioned and other officers of the United States Public Health and Marine Hospital Service for the seven days ending October 17, 1908.

ABROTT, F. C., Acting Assistant Surgeon. Granted four teen days' leave of absence from October 11, 1908.

BAILHACHE, P. H., Surgeon. Leave of absence for twenty days from September 21, 1998, amended to read fifteen

days from September 21, 1908, anended to read inteendays from September 21, 1908.

BURKHALTER, J. T., Passed Assistant Surgeon. Granted seven days' leave of absence from October 1, 1908.

FROST, W. H., Assistant Surgeon. Granted fifteen days leave of absence from October 11, 1908.

GIBSON, F. L., Pharmacist. Leave of absence for thirty days from September 8, 1908, amended to read sixteen days from September 8, 1908, amended to read sixteen days from September 8, 1908.

HEISER, V. G., Passed Assistant Surgeon. Granted thirty days' leave of absence while en route to join station at

Manila, P. I. Holt, E. M., Pharmacist. Granted thirty days' leave of

absence from October 19, 1908.

HOUGHTON, M. W., Acting Assistant Surgeon. Granted nine days' leave of absence from October 11, 1908.

KERR, J. W., Assistant Surgeon-General. Granted seven days' leave of absence from October 16, 1908.

MEGAW, H., Pharmacist. Leave of absence for thirty days from Sentember 1, 1908.

from September 1, 1908, amended to read twenty-one days from September 1, 1908.

Nydegger, J. A., Passed Assistant Surgeon. Leave of absence for twenty-three days from Septmber 19, 1908, amended to read twenty-two days from September 19, 1908.

ROGERS, EDWARD, Pharmacist. Granted three days' leave of absence from October 3, 1908, under paragraph 210, Service Regulations.

RYDER, L. W., Pharmacist. Granted two days' leave of absence from October 9, 1908, under paragraph 210, Ser-

vice Regulations.
MON, T. W., Passed Assistant Surgeon. Directed to SALMON. report to commanding officer revenue cutter Gresham October 10, 1908, for temporary duty. Scott, E. B., Pharmacist. Granted twenty days' leave of

absence from October 23, 1908.

SMITH, F. C., Passed Assistant Surgeon. Granted seven-teen days' extension of leave of absence from October

SPANGLER, L. C., Pharmacist. Granted thirty days' leave of

SPANGLER, L. C., Pharmacist. Granted thirty days' leave of absence from November 3, 1908.

STIMSON, A. M., Passed Assistant Surgeon. Directed to proceed to Santa Ana and points in vicinity of Los Angeles, Cal., upon special temporary duty.

STONER, G. W., Surgeon. Granted fifteen days' leave of absence from October 8, 1908.

TROXLER, R. F., Pharmacist. Leave of absence for seven days from September 28, 1908, amended to read five days from September 28, 1908.

Board Convened.

A board of medical officers was convened to meet at the Hygienic Laboratory October 19, 1908, on call of chairman, for the purpose of examining Pharmacist C. O. Sterns, to determine his fitness for promotion to the grade of pharmacist of the second class. Passed Assistant Surgeon J. F. Anderson, chairman; Passed Assistant Surgeon Joseph Goldberger, recorder.

Army Intelligence:

Official list of changes in the stations and duties of officers of the Medical Corps of the United States Army for the week ending October 17, 1908:

ADAIR, G. W., Colonel, Medical Corps. Granted leave of absence for fifteen days

BALLARD, J. C., First Lieutenant, Medical Reserve Corps. Ordered to active duty, and to proceed to Fort Sam

Houston, Texas, for duty,

BLANCHARD, R. M., Captain, Medical Corps. Ordered from

Fort Wingate, New Mexico, to Whipple Barracks, Arizona, for duty with troops on a twenty-one days' prac-

tice march.
Borden, W. C., Major, Medical Corps. Having been found physically incapacitated for active service, ordered home to await retirement.

Brechemin, Louis, Lieutenant Colonel, Medical Corps. Relieved from duty in charge of the medical supply depot, New York; granted leave of absence for one month, ten days; ordered to sail from San Francisco, Cal., for the Philippines on December 5th, instead of November 5th, as first ordered.

COFFIN, H. L., First Lieutenant, Medical Reserve Corps. Granted leave of absence for four months.

C. Le R., Captain, Medical Corps. Granted leave of

absence for ten days.

DAYWALT, G. W., First Lieutenant, Medical Reserve Corps, Relieved from present duties in time to sail on December 5th from San Francisco, Cal., for the Philippines. HARNNETT, E. H., Captain, Medical Corps. Relieved from duty in the Philippines Division in time to sail on January 1882.

uary 15, 1009, for San Francisco, Cal.

HENRY, Z. L., First Lieutenant, Medical Reserve Corps.

Assigned to active duty; ordered to Fort Thomas,

Assigned to active duty; ordered to Fort Finances, Ky, for active duty.

HUNTINGTON, P. W., Captain, Medical Corps. Relieved from present duties in time to sail on December 5th from San Francisco, Cal., for Philippine service.

LEECH, W. F., First Lieutenant, Medical Reserve Corps. Ordered to active duty, and to proceed to Jefferson December Medical Reserve.

Barracks, Mo., for duty. LORD, L. W., First Lieutenant, Medical Reserve Corps. Assigned to active duty and ordered to Fort Riley, Kansas,

for duty.

Love, A. G., Lieutenant, Medical Corps. Relieved from duty in the Philippines Division in time to sail on Jan-

uary 15, 1909, for San Francisco, Cal.
MALONEY, J. E., First Lieutenant, Medical Reserve Corps. Assigned to active duty and ordered to Fort Hancock, N. J., for duty.

MONCRIEF, W. H., Captain, Medical Corps. Relieved from present duties in time to sail on December 5th from San Francisco, Cal., for Philippine service.

PIPES, H. F., Captain, Medical Corps. Relieved from duty with Co. C, H. C., and ordered to duty at the Army General Hospital, Washington, D. C.

RAGAN, C. A., Captain. Ordered to return to Fort Monroe, Virginia, from treatment at Washington, D. C. RAND, I. W., Major, Medical Corps. Relieved from duty at the Philippines Division in time to sail on December

15th for San Francisco, Cal. PHERD, J. M., First Lieutenant, Medical Reserve

Shepherd, J. M., First Lieutenant, medical according Corps. Granted an extension of one month to leave of SLAYTER, J. T., First Lieutenant, Medical Reserve Corps.

Granted leave of absence for ten days.

SNYDER, H. M., Lieutenant, Medical Corps. Relieved from present duties in time to sail on December 5th from

San Francisco, Cal., for Philippine service.

Suggs, Frank, First Lieutenant, Medical Reserve Corps.

Granted leave of absence for one month, to take effect

about October 22d.
Torney, G. H., Colonel, Medical Corps. Granted leave of

absence for fifteen days.

WYETH, M. C., Major, Medical Corps. Having been found physically disqualified for the duties of a lieutenant colonel in the Medical Corps. by reason of disability incident to the service, his retirement from active service as a licutenant colonel is announced to date from May 1, 1908.

Navy Intelligence:

Official list of changes in the stations and duties of officers of the medical corps of the United States Navy for

BISHOP, L. W., Passed Assistant Surgeon. Detached from the Naval Flospital, New York, N. Y., and ordered to the Navy Recruiting Station, Omaha, Neb.

CUTHERTSON, R., Assistant Surgeon. Appointed as assistant surgeon from October 12, 1908.

DESSEZ, P. T., Passed Assistant Surgeon. Detached from duty at the Naval Hospital, Las Animas, Colo., and ordered to the South Dakota.

DIFILE, O., Medical Inspector. Commissioned a medical inspector from October 14, 1008.

inspector from October 11, 1908. EVANS, S. G., Surgeon. Detached from the Naval Hospital, Washington, D. C., and ordered to the *Pennsyl-*

GATEWOOD, J. D., Medical Inspector. Commissioned a medi-

cal inspector from September 18, 1968.

Hale, G. D., Assistant Surgeon. Detached from the Idaho and ordered to the New Hampshire.

Lownes, C. H. T., Surgeon. Detached from the South

Noble, D. H., Assistant Surgeon. Appointed an assistant

Rose, M. E., Assistant Surgeon. Detached from the Naval Recruiting Station, Omaha, Neb., and ordered to the

SHIPP, E. M., Surgeon. Detached from the Pennsylvania and ordered home to await orders.

SINCLAIR, J. A. B., Assistant Surgeon. Appointed an assistant surgeon from October 12, 1908.
WHITMORE, G. B., Assistant Surgeon. Appointed an assistant surgeon from October 12, 1908.

Births, Marriages, and Beaths.

Married.

ALLAN—Cowper.—In Buffalo, N. Y., on Wednesday, October 21st, Dr. Alexander Allan and Miss Maude Cowper. Barnes—Groves.—In Providence, Rhode Island, on Tuesday, October 13th, Dr. Henry Barnes, of Boston, and Miss

BLOOMBERGH-HOWARD.-In Atchison, Kansas, on Wednesday, October 7th, Dr. Horace D. Bloombergh, United States Army, and Miss Helen Howard.

CAMERON-NEWTON .-- In Washington, D. C., on Tuesday, October 6th, Dr. Frank Kenneth Cameron, of Baltimore,

October 6th, Dr. Frank Kenneth Cameron, of Baltimore, and Miss Virginia B. Newton.
COWLES—JAQUITH.—In Bridgeport, Connecticut, on Thursday, October 8th, Dr. Echward C. Cowles, of New York, and Miss Florence Jaquith. of Boston.
FLEMING—ELSTEIN.—In New York, on Thursday, October 15th, Dr. Mark E. Fleming and Miss Sarah Louise Elstein.
GILLS—THORNYON.—In Norfolk, Virginia, on Tuesday, October 6th, Dr. William Armistead Gills, of Richmond, and Miss Virginia P. Thornton.

HELLMAN-BLOOM.-In New York, on Monday, October 12th, Dr. Alfred H. Hellman and Miss Clarisse Bloom. LASHER—McLEAN.—In New York, on Wednesday, Oc-

tober 14th, the Rev. James Lewis Lasher and Miss Helen McLean, daughter of Dr. and Mrs. Malcolm McLean.

LINGENFELTER—GEARY.—In New York, on Wednesday, October 14th, Dr. Howard A. Lingenfelter and Miss Mar-

garet E. Geary.

Mesereau—Newbury.—In New York, on Wednesday, October 14th, Dr. William Jay Mesereau and Miss Josepha Myrta Newbury.

SLAUGHTER-McCoach.—In Philadelphia, on Thursday, October 15th, Dr. Charles H. P. Slaughter and Miss Caroline K. McCoach.

TOWNSEND—BURDICK.—In New York, on Wednesday, October 14th, Dr. Theodore I. Townsend and Miss Katherine Burdick.

ZURLO-VACHRIS.-In Brooklyn, on Sunday, October 11th, Dr. Lorenzo Zurlo and Miss Jennie Vachris.

Anderson.-In Louisville, Kentucky, on Tuesday, October 13th, Dr. Turner Anderson, aged sixty-six years.

Beck.—In New York, on Wednesday, October 14th, Dr. Alexander W. Beck, aged fifty-seven years.

CAMPBELL.—In Shelbyville, Indiana, on Thursday, October 8th, Dr. Frank Campbell, aged forty-six years.

Dearing.—In Braintree, Massachusetts, on Thursday, October 15th, Dr. T. Haven Dearing, aged eighty-three

GILE.—In Bloomfield, New Jersey, on Monday, October 12th, Dr. Francis Alfred Gile, aged sixty-three years.
GREEN.—In Geneseo, New York, on Tuesday, October

GREN.—In Geneseo, New York, on Tuesday, October 6th. Dr. Robert W. Green, aged sixty-eight years.

LAYBOURNE.—In Springfield, Ohio, on Thursday, October 8th, Dr. A. W. Laybourne, aged ninety years.

NEIMAN—In Philadelphia, on Thursday, October 15th, Dr. Howard G. Meiman, aged twenty-four years.

RAND.—In Washington, D. C., on Tuesday, October 13th, Dr. Charles Franklin Rand, aged seventy years.

RICH.—In Kennedy, New York, on Wednesday, October 13th, Dr. Filton S. Rich.

7th, Dr. Elton S. Rich.

RUSSELL,-In New York, on Wednesday, October 14th,

Dr. Herbert Russell, aged thirty-seven years.
Stewart.—In Clay Centre, Kansas, on Friday, October

STEWART.—In Clay Centre, Kansas, on Friday, October 9th, Dr. J. P. Stewart.
West.—In Jersey City, New Jersey, on Wednesday, October 14th, Dr. John Eberle West, aged sixty-five years.
Yarnogouch.—In Markham, Texas, on Saturday, October 10th, Dr. Henry E. Yarborough.

Original Communications.

THE ORIGIN OF SYPHILIS AND THE INVENTION OF ITS NAME.

Ву Јонн Клотт, А. М., М. D., Ch. В., and D. Р. Н. (Univ. Dub.); М. R. С. Р. І.; М. R. І. А., Etc., Dublin, Ireland.

The perennial interest which is inseparably associated with the subject of venereal disease; its bewilderingly protean and appallingly destructive manifestations; its obscure origin in time and space; and the inextricable entanglement of its phenomenal foulness and moral and physical degradation with the most exalted and exalting sentiments and the highest and holiest feelings experienced by fallen humanity, have effectively conspired to invest this scourge of our race with the polar contrasts of irresistibly attractive interest and loathsomely repelling disgust. Accordingly, its position in the public eye and mind, both lay and medical, is absolutely unique-and seems pretty sure to remain so. The recent (August 15, 1908) discussion of the inevitably evergreen subject by Dr. Merzbach in the pages of this Journal could not fail to fix the attention of the inquiring reader. thor accepts as final the historic view of "Dr. Iwan Bloch, a Berlin physician, possessed of astonishing industry, profound sagacity, and sound judgment in the study of origins"; one who, he proceeds to add, "entered upon his study of the origin of syphilis, having fully digested the material collected by his predecessors, and with a mental tenacity and thoroughness exceptional for even a German." This highly appreciative estimate appears to be well grounded. But the line should be drawn, surely, before arriving exactly at the erection of the claim to infallibility! And I hope to be able, in the course of the present communication, to lav before the readers of the New York Medical Journal evidence sufficient to show that the view of Dr. Iwan Bloch (and of his enthusiastic disciple), "eminently fitted for his task" as he admittedly is, cannot even now be accepted as "final." The professional jury of the Anglo-American world will thus be enabled, as I trust, to arrive at the formation of an intelligent and independent verdict; without unquestioning submission of their collective private judgment to that of any imported dictator, however "eminently fitted for his task."

Indeed, the interesting fact seems to remain still known but to the very small overinquisitive minor-

ity that the original appearance of the new born word syphilis was as the title of a poem-and a very brilliant one. This production was the work of an Italian, was written in Latin, and published in the year of grace 1530 at Verona-the native city of the author-in the form of a quarto booklet of thirty-six leaves. The epoch making production which has since that date come to form the nucleus of such a colossal mass of literature is decorated with an alternative title: Syphilis sive Morbus Gallicus. The gifted author was Hieronymus Fracastorius (Hieronimo Fracastorio). He was born in the year 1483, the same year in which Martin Luther and François Rabelais first saw the light; and he died in 1553, the year in which the latter peacefully paid the debt of nature, and Michael Servetus was burned for heresy. He accordingly lived in an age of phenomenal unrest, and—in a qualified sense—of enlightenment and discovery. When Fracastor was nine years old, Christopher Columbus sailed westward in search of a transatlantic route to the Indies; and two years later the famous epidemic which furnished the source of inspiration of his poem radiated from the siege of Naples. It was a generation of explosive research and of iconoclastic inquiry. An unprecedented conjunction of events of thrillingly concentrated importance was then registered in the annals of the nations; when Europe was almost simultaneously affected (and inflicted) by the conquest of a new enemy, the Turks; the discovery of a new continent, America; the infection of a new (?) disease, syphilis; the introduction of a new art, more revolutionary and levelling in tendency than any of its predecessors, printing; and the broadcast propagation of the various new theological doctrines which collectively came to constitute the so called "Reformation." The coincidence of the introduction of printing with the exodus of Greek scholars and Greek manuscripts from the capital of the Eastern Empire, which followed its capture by the Turks, resulted in the practical display of a fearful object lesson in the realization of the Cadmian allegory; it sowed all Western Europe with "dragon's teeth"! The series of successive and colliding and intersecting and impregnating waves of thought-theological and political, social and philosophical, scientific and literary, moral and immoral, which rapidly followed from east and west and south and north, rapidly produced the broadcast development of so great an amount of mental friction in all directions as to raise the temperature of the general intellectual atmosphere far above the

boiling point. And, as necessarily occurs during every process of violent ebullition, a large quantity of the veriest moral and intellectual dregs was brought to the surface and formed its distinctive topmost layer of floating scum; the general intellectual activity was, upon the whole, enormously increased; many wonderfully inspired bubbles were thrown up to a great height, and some of these displayed richly artistic colors before they burst or disappeared; while the really wholesome and nutritive strata of the seething liquid were those which never rose to meet the public eye. Indeed, there can be no question that, so far as historical record has shed its light on the pilgrimage of humanity, the age of Hieronimo Fracastorio was, intellectually and morally, the most interesting and exciting epoch that the world has yet seen. And this (once very) famous author appears to have been one of its most brilliant products. The fact that his name has so seldom been heard of in latter times is rather an indication of the decay of culture than of the growth of knowledge and expansion of intelligence within our professional ranks. His reputation, in his own day, appears to have been boundless as well as stainless; and he figured in the midst of a generation of intellectual giants and of dazzling, critical searchlights. As in the cases of other very celebrated personages of a period when miraculous records were not infrequent, and were readily received as reliably authentic, fame decorated the infancy of the author of Syphilis with some biographical items which heavily tax the mental receptivity of the twentieth century scientist. One of these testified that "his lips adhered so closely to each other when he came into the world that a surgeon was obliged to divide them with his knife"; and another is to the effect that "his mother was killed with lightning, while he, though in her arms at the very moment, escaped unhurt." We learn that: "He was of parts so exquisite and made so wonderful a progress in everything he undertook that he became eminently skilled, not only in the belles lettres, but in all arts and sciences. He was a poet, a philosopher, a physician, an astronomer, a mathematician, etc." The great importance attached to his opinion in the highest places is demonstrated by the fact that Pope Paul III. made use of his authority to remove the sittings of the Council of Trent to Bologna: Fracastorio having deposed that a certain contagious distemper had appeared which rendered it no longer safe to continue to hold its meetings at Trent. He was personally known to very many of the most distinguished men of his generation, and he received most appreciative criti--cisms from the tallest and strongest and most unsparing of the literary Brobdingnagians. Casar Scaliger "was not content to assert that he was the best poet in the world next to Virgil, but he affirmed him to be the best in everything else; and, in short, though he was not of a temper to give people more than their due, he is said to have adored Fracastorius." Indeed, of the whole of the contents of the three books of the epic poem on Syphilis, this mammoth of criticism falls directly foul of but one item, and that is one which by no merit. Fracastor had therein enunciated the view that the *morbus gallicus* confined its ravages to human beings exclusively. This statement is traversed by Scaliger, who (states that he) knew of a dog that had contracted the disease by licking the plasters which had been applied to his master's sortes.

Then we find a host of the other leaders of criticism in his own and the succeeding generation vieing with one another in their laudatory estimations of Syphilis and its accomplished author. Boissard tells us that his verses were compared to those of Virgil himself (Ejus poemata tanti fiunt apud omnes literatos, ut illa conferantur cum Virgilianis); and that he was, accordingly, worthy of the epithet of "the Divine," which was applied to him by many (weterna lande non sine causa ad calum evehantur, unde a multis DIVINUS vocatur Fracastorius). And Thuanus, the celebrated historian of that period, adds to the unlimited praise which he bestows on our author for his supereminent accomplishments in philosophy, mathematics, astronomy, and medicine, the statement that he always practised this last with the most brilliant success, and without fee or reward (et medicinam ut honestissime ac citra lucrum ita felicissime fecit)! The famous classical scholar, Lilius Gyraldus, is correspondingly laudatory; and Rapin, if possible, still more so, asserting that the Syphilis was the most exquisite poem which had been composed for ages, and constituted a successful imitation of Virgil's Georgies (tam felici successu concinnavit Syphilidis sua pama opus sane pulcherrimum quod postremis his sæculis elaboratum fuerit, latino carmine in Italia, quodque scriptum est ad imitationem Georgicon Vergilii). We learn from Vossius, after a similarly appreciative notice of our author's genius and attainments, that two years after his death, his fellow citizens of Verona-the romantically famous abode of the jealously vindictive Montagus and Capulets, and their ill fated victims, Romeo and Juliet-erected a marble statue to commemorate his nativity and well earned fame; as they had ages before treated with corresponding distinction the respective shades of their inspired Catullus and their encyclopædic Pliny (Cives sui l'eronenses defuncto, ut ante Catullo, ac Plinio, statnam marmoream statuerunt anno 1555). Ghilinus, the famous author of the Theatrum Virorum Literatorum, places still more prolonged and detailed emphasis on the eminence of Fracastorius as a medical man, and considered him well deserving of the epithet of Felix in his practice (Felicis Medici titulum sibi comparavit, quoniam in medicinæ exercitio magna utens dexteritate, et egregia curandi methodo, paneas habuit pares, seque amabilem et mirabilem omnibus præstitit, præsertim vero iis qui ob valetudinem ad ipsum confugiebant).

The second in importance—at least as to longitudinal dimensions—of the poetic effusions of Fracastor was one on the patriarch *Joseph*—which he commenced in old age, and did not have time to finish; and which is contrasted with the *Syphilis* in manner and execution almost as strongly as in matter. Each of these compositions was dedicated to a cardinal; the *Syphilis* to Cardinal Bembo, and the *Loveth* to Cardinal Larnese. He also composed a considerable munder of brilliant specimens of

minor poetry. The second collected edition of his works (Venetiis, aprd Juntas, M. D. LXXIII), which now lies before me, contains the following: INDEX OPERUM, QV.E IN HOC VOLVMINE CONTINENTUR.

Homocentricorum siue de stellis liber vnus.
De causis criticorum dierum libellus.

De sympathia & antipathia liber vnus.

vinus.

De contagionibus & contagiosis morbis, & eorum curatione libri tres.

Navgerivs siue de poetica dia-Tyrrivs siue de intellectione

dialogus. Fracastorivs siue de anima dia

De vini temperatura sententia. Syphilidis siue de morbo Gallico libri tres. Loseph libri duo. Carminum liber vnus.

There was published at a later date another (much admired) poem of our author, with the title of Alcon, sine de Cura Canum Venaticorum. Fortunately for me, an enthusiastic former owner of my copy has written out this document-in exquisite mediæval script—on the opening flyleaves. The fact of the survival of the high poetic reputation of Fracastor in the seventeenth century is fully proved by the inclusion of his poetical works—with the conspicuous exception of the *Joseph*—in the Delitiæ CC. Italorum Poetarum, hvivs svperiorisque ævi illustrium, collectore RHANVTIO GHERO. Cipioviii. And the prose works-medical, scientific, and philosophical-everywhere display a breadth and depth of penetration and reflection, and an inspiring suggestiveness of thought; features which I feel constrained, regretfully, to add are often quite conspicuously absent from the pages of the less original publications of recent "modern" "authori-The pages of the De Contagionibus et Contagiosis Morbis will be found by the earnest student who is qualified to scrutinize it, and can bring to bear on the examination sufficient contemporary and correlated knowledge to enable him to view the various aspects of the questions therein discussed from the standpoint of the writer, to scintillate in every direction with suggestive-even inspiringideas; of which some will, I venture to suggest, be pretty surely resuscitated; and with advantage to both scientific and lay public, when the latter day doctrine of the bacterial genesis of disease has ceased to occupy the position of an infallible item of pathological faith. The question as to whether the morbus gallicus

was a disease really new to Europe-dating its focal infection from the siege of Naples in 1494-in the generation of Fracastorio, is one which, as we have seen, has been very recently answered once more in the affirmative; and with the impressive aid of the most elaborate and demonstrative historical and critical machinery and method. As already mentioned, too, one of the special objects of the present communication is to show that this affirmative answer should not be regarded as final. Every intelligent reader will, I trust, be able to grasp the reasons and estimate the value of the facts placed before him by the present writer-who will then allow him to draw his own conclusions.

The story that the lues venerea was imported to Europe from Hayti by the crew of Christopher Columbus has, as all readers know, been repeated times without number; also, that the infection was communicated to their French besiegers by the

Spanish garrison of Naples, in 1494; and that from the latter focus it was rapidly dispersed throughout Europe. But—it was not till after thirty years had elapsed from the date of the introduction of the "French evil" into Italy, and its baptism with the name and surname of morbus gallicus, that the account of its importation from the New World appears to have found its way into printed literature, historical or scientific. During the first quarter of the sixteenth century-down to 1525, and, in some instances, even later still-the various medical authorities who wrote on the subject offered a variety (even to multitudinous complexity) of ingenious hypotheses and explanations of the genesis of the new venereal plague. The catalogue of causes is a long-even a gruesomely amusing-one; but the statement or suggestion of its transatlantic origin is quite conspicuously absent. Those of my readers who have some little knowledge of the hopelessly entangled connection of medicine with mysticism, metaphysics, theology, astrology, and alchemy, which prevailed during the artistically interesting ages of the ascendancy of scholasticism, are, of course, prepared to appreciate the central factor in the genesis and development of the semiinspired confidence with which two of the most prominent, and most learned, of the physicians of that age announced their belief that the origin of the epidemic outbreak of the "French disease" was traceable to the close conjunction of the sun with Mercury, Jupiter, and Saturn, which occurred in the year of grace 1483 (by a very curious coincidence, too, the year which saw the birth of the author of Syphilis -and inventor of the name-as well as that of Martin Luther, the strenuous human source of the epidemic of theological infection which so deeply affected the length and breadth of Christendom in the same generation!). But, as it so happened that the year in which the great initial epidemic of the morbus gallicus spread over Italy was also one characterized by exceptionally heavy rains and consequent inundations, the still more famous physician, Nicolaus Leonicenus, discarded that item of astral pathology which had been advanced by Corradino Gillini and Gaspare Torella, and substituted one derived from a less elevated (meteorological) stratum; that the outbreak of the foul disorder had been aboriginally engendered by the excessive amount of moisture which happened to be present at that date; in the heavens above, and in, as well as on, the earth beneath. The great reputation of the author of this hypothesis governed the opinions of very many subsequent "authorities." We afterwards find Manardi, and also Paracelsus, ascribing the origin of the new disease to the intercourse of a leprous male with a prostitute; the former knew of the case by personal acquaintance—the gentleman was a Valentinian by birth; the evidence in the possession of Paracelsus was of similar origin, but the male partner in his sexual group was of French nativity. The learned, and deservedly famous, Antonius Musa Brassavola, of Ferrara, informed the professional world that the original epidemic of the "malady of France" radiated from the person of a female camp follower of the French army at the siege of Naples. The female in question had suffered from an abscess at the mouth of the uterus.

But a widely divergent account of its source was furnished by Gabriel Falloppius of Modena, the celebrated anatomist and physician, whose name has become immortalized in connection with the human oviduct. He avers that the Spaniards, at the time when they were hard pressed by their French besiegers, poisoned the wells from which the latter obtained their water supply, and that the new epidemic disease was the direct result of that procedure. The celebrated physician of Pope Clement VIII., Andrea Cesalpino, one of the foremost claimants to the credit of the discovery of the circulation of the blood, tells us that he learned from those who had been present at the siege of Naples, and the other operations of that campaign, that the disease really originated at the siege of Somma, a village of the Vesuvian territory. A great quantity of an excellent (and highly appreciated) Greek wine was shut up therein. One night the besieged Spanish garrison managed to escape, leaving behind them the greater part of their wine, which they had taken care previously to mingle with the blood of the patients of San Lazaro. The French besieging force, on entering the deserted village on the following day, with the characteristic pillaging and self indulging instincts of "that dissipated nation," drank freely of the inoculated wine-after which they soon were attacked by venereal symp-

The learned Bolognese physician, Leonardo Fioravanti, states that he was informed by the son of a person who had been sutler to the army of Alfonso, King of Naples, that when the supply of meat began to run short on account of the prolongation of that war, his father (the sutler) supplied both camps with dressed human flesh disguised as ordinary meat. The unconscious cannibalism which was the result of the gruesome fraud thus perpetrated was, according to that authority, the immediate cause of the development of the original epidemic of morbus gallicus. The famous Lord Chancellor Bacon quotes this story, as he does so many other "old wives' tales," with patronizing credulity; and he takes the trouble, too, of filling in some details for the more complete enlightenment of his reader: that the human flesh supplied on the occasion was that of men who had been killed in Barbary, and that it had been prepared and dressed after the manner of tunny fish.

Whether the morbus gallicus was really a West Indian import, and one previously unknown on this side the Atlantic Ocean, were questions of frequent discussion-very evidently-in the days of the author of Syphilis; and which the reader of that "divine" composition will find referred to without any attempt at dogmatic decision. True to the tone and diction of his chosen epic, he closes the poem with a thoroughly poetic version of the first appearance of the epidemic, almost as classic and pagan as his great prototype, Virgil, could himself have made it. This would seem to imply an intention of leading the reader to believe in the antiquity of its European existence. The lines are thoroughly worthy of the attention of every reader who is interested in the history of the healing art, as every medical man worthy of his profession must always be; and more especially having regard to the fact

that the origin of the word Syphilis has proved as ideally effective a pons asinorum to medical etymologists, as the origin of the protean pathological entity which it connotes has been to medical annalists. And they are as follows:

Syphilus (vt fama est) ipsa hæc ad flumina pastor Mille boues, niuas mille hæc per pabula regi Alcithoo pascebat oues, & forte sub ipsum Solstitium vrebat sitientes Syrius agros: Vrebat nemora: & nullas pastoribus vmbras Præbebant syluæ: nullum dabat aura euamen, Ille gregem miseratus, & acri concitus æstu, Sublimem in Solem vultus & lumina tollens Nam quid Sol te. inquit, rerum patremque Deumque Dicimus, & sacras vulgus rude ponimus aras, Mactatoque boue, & pingui veneramur acerra, Si nostri nec cura tibi est, nec regia tangunt Armenta? an potius superos vos arbitrer vri Inuidia? mihi mille niuis candore iuuencæ, Mille mihi pascuntur oues: vix est tibi Taurus Vnus, vix Aries cœlo (si vera feruntur) Vnus, & armenti custos Canis arida tanto. Demens quin potius Regi diuina facesso, Cui tot agri, tot sunt populi, cui lata ministrant Æquora, & est superis, ac Sole potentia maior Ille dabit facilesque auras, frigusque virentum Dulce feret nemorum armentis, æstumque leuabit. Sic fatus, mora nulla, sacras in montibus aras Instituit regi Alcithoo, & diuina facessit. Hoc manus agrestum, hoc pastorum cætera turba Exequitur: dant thura focis incensa, litantque Sanguine taurorum, & fumantia viscera torrent. Quæ postquam rex, in solio dum forte sederet Subjectos inter populos, turbamque frequentem, Agnouit, Diuum exhibito gauisus honore Non vllum tellure coli se vindice numen Imperat, esse nihil terra se maius in ipsa: Cœlo habitare Deos, nec eorum hoc esse, quod infra est. Viderat hæc, qui cuncta videt, qui singula lustrat, Sol pater, atque animo secum indignatus, iniquos Introrsit radios, & lumine fulsit acerbo. Aspectu quo Terra parens, correptaque ponti Aequora, quo tactus viro subcanduit aer. Protinus iliuuies terris ignota profanis Exoritur, primus, regi qui sanguine fuso Instituit diuina, sacrasque in montibus aras, Syphilus ostendit turpes per corpus achores Insomnes primus noctes, consulsaque membra Sensit, et a primo traxit cognomina morbus, Syphilidem que ab eo labem dixere coloni.

Thus, according to the conception of Fracastorio, the original plague of syphilis was a visitation of the offended solar deity; just as was that which opens the action of the *Iliad*—the complications of which led to the development of "Achilles' wrath"! So the arrows of the "far darting Apollo" were tipped for the occasion with a special culture of the bacillus of Lustgarten, or of the *Spirochata pallida* of the most recent apostles of bacteriological pathology!

As the author of Syphilis has not confided to his readers the stages of the mental process by which the name of his afflicted hero was evolved, a difficulty has necessarily arisen in regard to the determination of its probable or possible etymology. The very obvious derivation from σ^{in} (with) and ψ^{ij}_{c} (loving) readily suggests itself; and has indeed been, with a very plausible appearance of probability, received with the largest proportion of favor. But a more tortuous origin has been subjected to critical approval—from σ^{in} (hog) and ψ^{ij}_{c} This latter derivation is, of course, sugestive of bestiality, and of the most revolting kind. And although some would fain refer its original suggestion to the limbo of etymological mare's nests, it must be ad-

mitted that this derivation has received ingenious corroboration from some Levantine traditions relating to the association of bestial indulgence with venereal disease. After all, however, although the word has a Greek aspect, and was, accordingly, appropriately placed in a poem constructed after a classical model, it has not a self supporting Greek basis. We should probably, I venture to suggest, be right in regarding its formation as a specimen of poetic license. If either of the above mentioned derivations was really accurate, the resulting word should have been, for the first, Symphilus; for the second, Syophilus.

The origin of the adhesive appellation of morbus gallicus, which became so popular soon after the appearance of the great epidemic, must, of course, be referred to national antipathy. And this was by no means the sole epithet of corresponding derivation. The French gave it the name of morbus neapolitanus from the locus of its supposed nativity. From its traditional Spanish-American importation it received the compound epithet of scabies hispanica. The racial antipathies of dirt throwing patriots transferred the association of the disease and its name to those nationalities which they most detested. Accordingly, the more widely diffused Gallic cognomen was sometimes freely translated into German, Polish, Turkish, etc. although the Turks-for be it remembered that this was the precise period in which they had just come into broad contact with Europeans for the first time in their national history—retaliated with the reproachful epithet of "the Christian disease"! And so all around the ring; another item of evidence corroborative of the unity-without unionof the whole human race!

It is, of course, now well known to all well informed readers that the questions of the antiquity, and cosmopolitan distribution, of the lues venerea have been very frequently, and, for the most part, rather inconclusively discussed, even in general, as well as medical literature. Its modern origin must, I have always thought, strike the skilled pathologist as extremely unlikely. The Biblical writers and classical authors furnish, indeed, some very suggestive allusions. Gleaners in the wealthy harvest of the "higher criticism" know that some contributors have suggested that the "great plagues" with which the Lord plagued Pharaoh and his house, "because of Sarai, Abram's wife," can have been no other than venereal. The most learned and copious of the Jesuitical commentators on the book of Job has discussed at great length the nature of the physical afflictions of that patriarch, and arrived at the opinion that they were truly venereal. Even the agonizing appeal of the inspired Psalmist himself-which followed his first meeting with Bathsheba: "Heal me, O Lord, for my bones are vexed," has aroused the most compromising suspicions. The idea of the association of the lesions of venereal disease with the sufferer of proverbial patience was so firmly rooted in the Italian mind at the time of the outbreak of the historical epidemic of the morbus gallicus that we possess the testimony of the contemporary authority, Fulgentio, to the fact that, even from the beginning, some called the new plague "morbus Sancti Jobi." It should here be mentioned that the names of some other saints became subsequently attached to the disorder; it has been referred to, at various times and by various writers, as the "disease of St. Mevius," "disease of St. Roch," "disease of St. Sementius," etc., etc.

The classical allusions to symptoms and lesions of probably venereal origin are, it must be admitted, comparatively few—even in the least restrained compositions of Juvenal and Martial. But the lines of Catullus, the ancestral fellow citizen of Fracastorio—in which he so ruthlessly attacks the morals of Julius Cæsar, are unquestionably very suggestive:

... maculæ pares utriusque Urbana altero, et illa foramina, Impressæ resident nec eluentur.

And with regard to the existence of venereal disease in mediæval times, the descriptions and allusions of Avicenna, Albucasis, Gulielmus de Saliceto, Lanfranc, John of Gaddesden, etc., etc., are far too definite and pointed to be meant for anything else than groups of lesions very similar, at least, to those included in modern times under the generic appellation of syphilis. We find that in the year 1302 diseases of the genital organs had become so common in Venice that a fine of twenty soldi was imposed-for each individual offense-on every person who was convicted of having been the agent of communication. Towards the close of the same (fourteenth) century, Valesco mentions pustules and ulcers of the penis, which he attributed to *coitus* cum fætida, vel immunda, vel cancrosa mulierc. And the preventive treatment of John of Gaddesden would seem to be almost as prophetic of twentieth century practice as his scarlet treatment of smallpox: Si quis vult membrum ab omni corruptione servare cum recedit a muliere quam suspectam de immunditia, lavat illud cum aqua frigida cum aceto mixta, vel de urina propria interius vel exterius intra præputium.

An expression of opinion which can, as it seems to me, be very plausibly defended in the light of our present knowledge, was advanced by Lane in the pages of the Lancet some fifty-seven years ago: "That the venereal disease had existed for centuries prior to the siege of Naples, not only in South America, but in all parts of the world wherever promiscuous sexual intercourse, unrestrained by religion or by the customs of society, was carried to great excess. . . . that the discovery made at this period consisted simply in the recognition of a peculiar animal poison as the cause of various symptoms affecting different tissues of the human body, at considerable intervals of time, which symptoms had not been previously known to have any relation to each other." And if we add to this extreme probability the fact-not generally discussed in the manuals of surgery, and never, so far as I know. in those of bacteriology—that a more destructive type of venereal disease tends to develop from inoculation with the virus derived from an individual of a remoter race, we have, I venture to think, the double key required to unlock the historical mystery of the rejuvenescence, after the discovery of the New World, of the disease which inspired the epic muse of Hieronimo Fracastorio. The "Swan Alley sore" of the days of Benjamin Travers was immeasurably more-and more rapidly-destructive in its progress than any average London chancre; for it was the fruit of the continuous patronizing culture of the foreign sailors and refugees who were derived from the veriest social and moral dregs of the population of all foreign countries. And the ravages of the "black lion" of the Peninsular War, which caused, in so many cases, the infliction of "that most melancholy of all mutilations" on the elect members of "the flower of England's chivalry," were said at the time to have emanated from the desired person of a magnificently fascinating Spanish beauty who appeared every night on the stage in a state of apparently unsuspicious health. Is not this historic item a replica of the "original" Spanish importation of the lues venerea, rather more than three centuries before?

The view which I have thus ventured to express would, I think, satisfactorily account for the apparent indiscrepancies which appear to cloud and confuse the historical luminosity of the annals of venereal disease. It would reconcile the reports of its previous existence in the Old World, and its unlimited dispersion throughout all the regions thereof, with an abrupt outbreak of a more virulentrejuvenated-type of the disease after the discovery of the New World by Christopher Columbus and his Spanish sailors. We are in possession of thoroughly respectable and apparently unprejudiced testimony to the existence of the venereal disease in various remote regions of the Old World, in the older periods of its history. For instance, the famous French geographer, André Thevet, informs us that the "French disease" was endemic in Africa, throughout the regions bordering on the River Senegal. I. Bonzius, who occupied the post of French physician to the Dutch settlement in the East Indies, states that the same disease was endemic in Amboyna and in the Moluccas. Cloyer, the first physician of the Dutch colony in Java, tells us that the venereal contagion was a natural endemic product of that vast island, and as common and well known there as the quotidian ague. And we are informed by Herrera that Magellan and his crew, in the course of the first circumnavigation of the globe, landed at Timor, an island of the Moluccan Archipelago, where they found a large proportion of the native inhabitants affected with the lesions of the morbus gallicus, although they had been, up to that date, absolutely unacquainted with Europeans of any and every nationality. Astruc, the author of the celebrated classical work on lues venerea, interrogated Père Forneau on the subject of the antiquity of the existence of the venereal disease in the eastern hemisphere-who had long resided among the Chinese and had investigated their customs and penetrated their secrets as only a French Jesuit can. And he was told that the Chinese physicians believed that the disease had existed in their country from the very earliest antiquity-the authors of their oldest books referring to it as an ancient disease. So I ventureand with considerable confidence-to think that the collective statements of these witnesses (a few, only, abstracted from the available multitude) should satisfy all inquirers as to the actual antiquity of the lucs venerea.

Before dismissing the subject of syphilis, and the inventor of the appellation by which the protean disease has long been universally known, I will give an extract from the encyclopædic Bayle, which will, I trust, interest the reader—offering, as it does, an excellent view of the name and fame of the author of the uniquely inspired epic poem and his work; while displaying the genesis of a jealous French growl elicited by the nomenclature of the disease which the author had undertaken to describe in a way so thoroughly unprecedented, and an attempt to retaliate by the substitution of the term Neapolitan for Gallic in the malodorous epithet:

We can hardly forgive Fracastorius for his poem upon that vile distemper, which he ought to have treated only as a physician. If he had acquired a great fortune by curing this terrible effect of debauchery, there would have been something to be said. He might have urged that he displayed his poetic talent upon this Neapolitan Evil to testify his gratitude for the services it had done him; and we might, perhaps, have cited him along with the surgeon who, on being reproved for kneeling down to the statue of Charles VIII, answered that he knew very well what he did, and that there was no saint to be held in greater veneration than a prince who had, though indeed indirectly, enriched him by the distemper which his soldiers had caught at Naples; but, practising always for nothing, he had no such pretence. To be serious, the Syphilis is an incomparable poem; and charmed to admiration the two Scaligers, Sannazarius, and others, the severest judges, Fracastorius would needs compose another poem, and he chose for his subject the adventures of the patriarch Joseph, but the season for making verse was over with him, and he no longer felt that fire and vigour of imagination which he had shown in his fermer years.

Hieronimo Fracastorio died of apoplexy at Casi, near his native city of Verona. His enthusiastic admirer, Julius Cæsar Scaliger—the famous (and usually merciless) critic of that generation—had dubbed him, during life, præstantissimus post Virgilium poetarum, and referred to his Syphilis as the poema divinum. And the same unrivalled hand penned the author's epitaph in the following lines:

Hie situs est Fraeastorius Hieronymus: urna Quem capit, hic cepit pectore cuncta suo. Sidera digessit: revocavit funera, rerum Naturæ, imperii conscius, atque Dei. Aut Heliconiadum fontem sibi sustulit omnem Aut tumulus vertex hic Heliconis erit. 34 YORK STREET.

PRECIPATE REACTIONS WITH LECITHIN, SO-DIUM GLYCOCHOLATE, AND SODIUM TAUROCHOLATE FOR THE DIAGNOSIS OF SYPHILIS.

> By WILLIAM J. BUTLER, M. D., Chicago, Attending Physician, Cook County Hospital, AND W. T. MEFFORD, M. D., Chicago.

Since the discovery by Wassermann (1), with Neisser and Bruck, of the serum reaction for syphilis, based on the complement deviation principle of Bordet, numerous researches have been carried on to determine the identity of the substances contained in the extracts used in the reaction, and also to simplify the test.

As a result of these and partially as a result of experiments based on different lines of reasoning, other reactions have been advanced for the diag-

nosis of syphilis. While the principles on which these reactions depend apparently vary, the result

in each instance consists of a precipitate.

Fornet (2) and Schereschewsky, proceeding from the assumption that the sera of patients with florid syphilis contain precipitinogen, and that the sera of parasyphilitics contain precipitin, found that on bringing together in a test tube carefully so as to form separate strata, the serum of a case of florid syphilis and that of tabes or paresis progressiva, the latter serum to be used pure and in different dilutions with distilled water: namely, 1:5 and 1:10, a precipitate either formed immediately or in the course of two hours, at the line of contact. Plaut, Heuck, and Rossi (3), who tried this method, reported it as inconstant and obtainable with some normal sera.

Michaelis (4) observed in one instance a precipitate to occur after mixing a syphilitic serum with

luetic organ extract.

Klausner (5) reported that on mixing luetic serum with distilled water in the proportion of 0.2 c.c. to 0.7 c.c. a precipitate occurred at room temperature in from one to fifteen hours. Klausner (6) later reported that he obtained the reaction with cases of various other infectious diseases, as pneumonia, typhoid, lupus, etc. (In this communication he advised the proportion of 0.2 c.c. serum and 0.6 c.c. distilled water.)

Our own experience with this reaction has been very unsatisfactory. We found a reaction in a very small proportion of cases we examined. Klausner attributes this to not examining the fresh sera, stating that the serum should be examined shortly after taking blood from the patient. The reaction is said to depend on the precipitation of globulin, which is increased in infections, consequently the reaction is obtainable in other diseases, and is not specific for

syphilis.

Wassermann (7), with Porges and Meier, as had also Landsteiner (8), Müller and Pötzl and Levaditi (9), and Yamanouchi, found that the alcoholic organ extracts contained the active organ substances concerned in the serum reaction for syphilis. Being soluble in alcohol, it was assumed they were lipoids. Therefore, Porges and Meier experimented with a lecithin suspension, substituting the same for organ extract in the serum reaction, and obtained the reaction with luetic sera. found similar results with solutions of sodium glycocholate and taurocholate. Porges and Meier (10) observed that on mixing a 0.2 per cent. suspension of lecithin with luetic sera in some cases a precipitate formed after standing for fifteen to twenty hours at room temperature, or several hours in an incubator. Porges (10) and Meier found the lecithin reaction in one hundred cases of lues, on which they reported, to coincide closely with the results of the serum reaction for syphilis.

From the work of Fritz and Kren (11), Noble

From the work of Fritz and Kren (II), Noble and Arzt (I2), Eisler (I3), Weil and Braun (I4), etc., it soon became evident that the lecithin reaction was obtained with the sera of patients suffering from other infectious diseases, as tuberculosis, in about as large proportion as in syphilis, also in

malignant growths.

Fritz and Kren reported more favorable results

with sodium glycocholate, obtaining positive reactions in only eighteen per cent. of the tuberculosis cases they examined.

Elias (15), Neubauer, Porges, and Salomon have recently reported the results of their work with sodium glycocholate, controlled by the serum reaction. They obtained fifty per cent. of positive reactions with the serum test, and forty per cent. with the glycocholate of sodium. This comparatively small percentage is due to the fact that questionable and latent cases of syphilis made up a good share of the patients examined. Among their seventy-seven control cases, there were eight positive with the precipitate, and fourteen with the serum reactions. They expressed doubt as to some of the control patients that gave a positive test, being free from syphilis.

Prior to the appearance of this latter report we had under way a series of examinations of syphilitic, parasyphilitic, and control cases, in which we used with few exceptions for each serum the following tests: I, The serum reaction. 2, The precipitate tests, with, a, lecithin, b, sodium glycocho-

late, and, c, sodium taurocholate.

The first reported results with sodium taurocholate as a precipitating reagent for syphilitic and parasyphilitic sera, are, so far as we can determine, contained in this paper. Levaditi (9) and Yamanouchi used this salt with satisfactory results as a substitute for syphilitic liver extract in the serum reaction.

The first of these tests, namely, the serum reaction for syphilis, was described by Butler in the Journal of the American Medical Association, September 5, 1908, to which the reader is referred for information concerning it. The performance of the precipitate reactions are comparatively easy and unattended with the many difficulties confronting one in making the complement deviation test.

The precipitate test is made by mixing equal quantities of the serum to be examined, and the precipitating reagent in a test tube, and allowing them to stand at room temperature for from fifteen to twenty hours. If the reaction was positive, a precipitate will have formed and collected at the top of the fluid, and on slightly tapping the tube it will descend in flocculi or whitish clouds from the surface. Vigorous shaking of the tube often diffuses the precipitate, rendering the fluid turbid. Turbidity of the fluid alone is not diagnostic. was noticed that in a few control cases of acute infections a precipitate formed and settled at the bottom of the tube and became evident only on shaking. The reagents used in the precipitate tests consist of (1) a 0.2 per cent. suspension of lecithin, made by adding one gramme of lecithin to enough warm alcohol to dissolve it and then adding enough distilled water to make up 500 c.c.; (2) sodium glycocholate; and (3) sodium taurocholate solutions made in the strength of one per cent. in distilled water. The latter are perfectly clear solutions when made, but become turbid on standing twenty-four hours, when they are unfit for use. They, as well as the lecithin suspension, should be made immediately before using. Elias (15), Neubauer, Porges, and Salomon consider much depends on the preparation of lecithin used for the test.

They recommend Kaulbaum's lecithin, and attribute some of the discrepancies with this reaction to using other makes of the preparation. We have used Merck's preparation of lecithin, and glycocho-

late and taurocholate of sodium.

The blood is either taken from a vein by a hypodermic needle of good size calibre, or from the finger, which should be constricted by a bandage and pricked with a fine pointed lancet. It is collected in a sterile test tube. The blood may be centrifuged at once, or allowed to stand until the serum separates, which should be removed by a pipette, and if not clear should be centrifuged and the clear serum only used. A turbid serum is not suitable for the reaction.

Some authors have used only sera which has not been inactivated (inactive serum is serum that has been heated to 56° C. for half an hour) in their experiments with the precipitate reactions. Elias (15), Neubauer, Porges, and Salomon state that the greater number of their tests were made with active sera, but thought that if they had used the inactivated sera, as they had in the last sixty-eight of their cases, better results would have been obtained. In view of this uncertainty as to the state in which the sera might best be used for the reactions, we divided each serum into two portions, inactivating one and leaving the other active, and made each precipitate test with the active and inactive sera. with few exceptions, of all cases that we examined in order that we might compare their respective merits. We used from 0.4 c.c. to 0.8 c.c. of serum in each of these reactions, depending on the quantity of serum available.

We examined (see colume I of the table) the sera of seventy-four cases, thirty-eight of these were made up of patients with primary, secondary, and tertiary syphilis, visceral syphilis, and parasyphilitics. The remainder were controls, the diagnoses of which are mentioned in the table. The results of the several reactions for each serum are indicated in parallel columns. In several instances there was insufficient serum for all the tests. These are indicated by ciphers. The plus and minus signs mean positive and negative respectively, and refer

to the result of the reactions.

In Table 2 is given the per cent. of positive reactions obtained by the different tests for the first, second, and third stages of syphilis, and for visceral syphilis and parasyphilitics. Under "Total I" is given the percentage of positive reactions for all cases of manifest syphilis with the serum and precipitate reactions, and under "Total 2" the percentage of positive reactions with manifest and with viscereal syphilis and parasyphilitics is pre-

sented.

In the examination of control sera, it was found that four of the patients with tuberculosis, all of which were in the third stage of the disease, gave a positive "serum reaction" for syphilis. Investigation of these cases revealed the fact that all four had syphilis. One case of typhoid and one of pneumonia gave a slight reaction with this test when guinea pig heart was used as antigen. On subsequent examination, of the same sera during convalescence of patients, on using syphilitic liver extract as antigen, they were found negative. Sodium

glycocholate gave a positive reaction with the active serum of one and inactivated serum of another case of typhoid fever, and of one case of tuberculosis that had syphilis. The active and inactive sera of one typhoid proved positive with sodium taurocholate, also the active serum of another and the inactive serum of a third typhoid case proved positive; also one tuberculous case that was syphilitic.

Lecithin gave a positive reaction with the active and inactive sera of sixteen and seventeen control cases respectively, and three cases of tuberculosis with syphilis. Five of the active and six of the inactivated sera of eight cases of carcinoma gave, a

positive reaction with lecithin.

Weil (14) and Braun assumed, on the basis of a number of positive results obtained by lecithin with the blood serum of cases of malignant growths, that these positive reactions with lecithin supported the bacteriological theory of malignant tumors. We obtained a positive reaction with a 0.2 per cent. suspension of lecithin in a case of syphilophobia that was negative to all other reactions. Our results in carcinoma cases are similar to those of Stumme (16), who found eight of ten cases of cancer positive with the lecithin test. One of our cases of carcinoma of the breast that had not ulcerated gave a positive reaction. The deductions, as made by Weil and Braun, seem unwarranted from our experience with the lecithin reaction.

In the results obtained by the various tests with active syphilis, parasyphilis, etc., it will be noted that ninety-three per cent. of the cases of active syphilis gave a positive reaction with the complement deviation test. In the same cases sodium glycocholate gave a positive reaction in fifty-seven per cent. with the active sera, and seventy-nine per cent. with the inactivated sera; sodium taurocholate in fifty-five per cent. with the active sera and sixty-one per cent. with the inactivated sera; lecihin, under the same circumstances, showing nine-ty-one per cent. and ninety-six per cent. of positive

reactions.

In the viscereal and parasyphilitic cases the serum reaction showed up best with seventy-seven per cent. of positive results, while the glycocholate was positive in twenty-one per cent. and thirtythree per cent., the taurocholate in thirty-three per cent. and fifty-five per cent., and lecithin in sixtysix per cent. and fifty-five per cent. with the active and inactivated sera, respectively. The results in the parasyphilitic cases reduced considerably the total number of positive results with the glycocholate in contrast to the serum reaction, which gave ninety per cent. of positive reactions for all cases of syphilis and parasyphilis examined, the glycocholate showing forty-eight and sixty-eight, the taurocholate fifty and sixty, and the lecithin seventysix and eighty-five per cent. with the active and inactivated sera respectively.

Summary.—The serum reaction surpasses in the percentage of positive results, and in reliability the precipitate reactions with lecithin, sodium glycocholate, and sodium taurocholate for syphilis and parasyphilis. The glycocholate and taurocholate of sodium, especially the former, show a large percentage of positive results in manifest syphilis and a remarkably small percentage of positive reactions

in control sera. Of these reagents the taurocholate gives the best results, in positive reactions with

parasyphilitic sera.

While the lecithin test compares favorably with the serum reaction in positive results in syphilitic and parasyphilitic cases, fully fifty per cent. of the control cases proved positive with lecithin, thus rendering it absolutely unreliable and definitely

nonspecific for syphilis.

The results obtained in the control cases with active and inactivated sera were practically alike with glycocholate and taurochalate of sodium, but in the syphilitic and parasyphilitic cases the inactivated sera gave the greatest number of positive results by thirty per cent. with the glycocholate and by seventeen per cent. with the taurocholate of sodium. This indicates that the results of the reaction in nonsyphilitic patients are equally reliable with either the active or inactivated sera, but a positive reaction is far more frequently obtained in syphilitic and parasyphilitic patients with the inactivated sera.

The glycocholate and taurocholate reactions will have to be tried out by many investigators before their real value in the diagnosis of syphilis can be determined. The results of our examinations, however, were especially satisfactory with these reagents in view of the few positive reactions obtained with these salts in the controls examined.

THE POPULAR LECTURE IN THE CRUSADE AGAINST TUBERCULOSIS*.

By S. Adolphus Knopf, M. D., New York,

Professor of Phthisiotherapy at the Postgraduate Medical School and Hospital; Associate Director of the Chine for Pulmonary Diseases of the Health Department; Visiting Physician to the Riverside Sanatorium for Consumptives of the City of New York.

Valuable as the distribution of literature always has been and will be to enlighten the people on subjects of hygiene and the prevention of disease and although the interesting and instructive leaflets on the prevention of tuberculosis have proved to be of incalculable benefit, the spoken word, the verbal instruction to the individual, or the popular lecture to the masses, has a most important mission to fulfill

in this crusade against tuberculosis.

While it is by no means essential that such a lecture should always be delivered by a physician, in smaller communities, where the lecturer is likely to be personally known to a large number of the audience, the local physician's words will be listened to, perhaps, with greater attention and respect than those of a layman. If there is a local antituberculosis committee the lecturer should be a member of it, and if, as is of course desirable, several physicians belong to the association, they should alternate

in lecturing. A public hall, schoolhouse, or church, easily accessible, well lighted, and well ventilated, is of course the most suitable place for this purpose. It will not do to lecture on tuberculosis, and on the value of light and pure air, in a gloomy, badly ventilated hall. The lecture must be free to all and delivered at a time when the masses can come to listen. The titles of the lectures should not be gruesome; they should be dignified, encouraging, and inviting, for example like the following, which the writer has used with success: Our Duties toward the Consumptive Poor. The Tuberculosis Problem and How It May Be Solved. The Prevention of Tuberculosis. The Joyful Message of the Preventability and Curability of Tuberculosis. Pulmonary Consumption and the Possibilities of Its Eradication through the Combined Action of a Wise Government, Well Trained Physicians, and an Intelligent People. The Victory over the Great White Plague. The Social and Humanitarian Aspects of the Tuberculosis Problem. The Duties of the Government and the Individual in the Combat of Tuberculosis. The Successful Warfare against Tuberculosis.

If the audience is to be composed of women or schoolteachers, it is well to select titles similar to the following: Women's Duty in the Fight against Tuberculosis. The Teacher's Part in the Antituberculosis Crusade. Or if the audience is composed of laborers, it is well to use a title similar to this: What Can Workingmen Do to Fight Tuberculosis among Themselves?

The handbills, circulars, or cards inviting a general or a special public to attend a lecture should be attractive and to the point. If it can be an-

COLUMBUS BOARD OF TRADE.

Governor Herrick will preside and introduce the speaker. NO ADMISSION CHARGED. You are cordially invited to attend, and bring your friends.

Very respectfully, JOHN Y. BASSELL R. GROSVENOR HUTCHINS

ATTENTION! CLOTHING WORKERS!

If you wish to learn how to guard against the dreadful dis-ease of consumption which is very common among the tailors and which can be easily pre-vented, come to the

MEETING which will be held on SUNDAY EVE., MARCH 13th

EDUCATIONAL ALLIANCE HALL,

Jefferson St., corner East Broadway.
Professor Jacobi, Dr. David Blaustein, Mr. Joseph Barondess,
Mr. Paul Kennaday, and other prominent speakers
will address the meeting.

Mr. Henry White will preside.

ALL ARE WELCOME.

Under the auspices of the United Garment Workers of America, and The Committee on the Prevention of Tuberculosis.

CONSUMPTION.

WILL YOU HELP TO DRIVE THE DISEASE FROM OUR CITY?

WHY? LEARN

HOW?

nounced that a prominent officer or a particularly honored citizen or preacher of the city or State will preside over the meeting, it will add to the prestige of the movement and be likely to attract a larger audience.

Advent delicated before Section V. Hygiene, Social, Industrial and Leonomic Apoets of Tuberculous of the Fourth International Congress on Tuberculosis, Washington, D. C., October 1,

I have given here three examples of invitation cards which should be issued. They are a card of invitation issued by the Columbus Board of Trade, a handbill inviting the clothing workers to a lecture on the prevention of tuberculosis, issued by the United Garment Workers of America and the Committee on the Prevention of Tuberculosis of the Charity Organization Society, and an excellent and attractive circular issued by the Newport Association for the Relief and Prevention of Tuberculosis.

It has sometimes been the experience of the writer, as an occasional lecturer before public audiences, to be requested by the committee on arrangement to avoid the word tuberculosis or consumption in the title of his lecture. It was thought by the committee that too suggestive titles might keep a number of sensitive people away. Such titles as, for example: How May the Health of Our Community be Improved? A Health Problem of Interest to Everybody. Health and Prosperity and How It May be Furthered, might then be used.

In a public lecture on tuberculosis it is well to point out strongly the economic loss accruing to a community which does not take care of its consumptive poor at the right time and at the right place, when there is the best possible chance for recovery, but wait until it is too late and then cares for them at the wrong place (county hospital or poor farm). It is best to make such calculations with direct reference to the locality in which the lecture is delivered. Thus, for example, in my own city and State of New York I have been in the habit of giving to my lay audience the following convincing figures: It is estimated that there are in this State about 50,000 tuberculous invalids. Of these probably one fifth belong to that class of patients which sooner or later become a burden to the community. These 10,000 consumptives, absolutely poor, will sooner or later have to be taken care of by the public general hospitals. While they may not stay in one hospital twelve months continually. they will certainly occupy a bed in one or other of the public institutions for that length of time before they die. According to a recent report by the public charity hospitals of New York city the average cost per patient per day in the general hospital is Thus, the cost to the commonwealth will be \$4,234,000 per year for caring for the 10,000 consumptives. What would be the expense if they were taken care of in a sanatorium? Experience in this country has demonstrated that the maintenance of incipient cases in well conducted sanatoria can easily be carried out for \$1 per day. If these 10,000 persons could be sent to a sanatorium in time, at least 6,000 of them would be lastingly cured after a maximum sojourn of 250 days, at an average expense of \$250 per caput. Thus for \$1,500,000 6,000 persons could be made again breadwinners and useful citizens. If the remaining 4,000 invalids were kept in the sanatorium one year before they died it would cost \$1,460,000. Thus, taking away from the tenement district 10,000 consumptives, curing more than half of them, caring for the other half, and destroying 10,000 foci of infection will cost \$2,960,000, when not taking care of them in the earlier stages of this disease they will probably

all die, since this 10,000 represents the absolutely poor, who now live under most unhygienic conditions-they will have infected a perhaps equally large or larger number of individuals living with .them, but before dying they will have cost the community \$4,234,000.

Another valuable argument which may well be presented in any public lecture is that relating to the loss which accrues to a community by failing to prevent its people from becoming tuberculous. Besides the loss and sorrow which are naturally felt by the individual and family, the economic loss from tuberculosis sustained by the commonwealth is tremendous. Dr. Thomas Darlington, the health commissioner of New York city, in speaking of the cost of tuberculosis in that city, declares in a recent publication: "Estimating the value of a single life at \$1,500-not necessarily a high estimate -and taking only the lives between sixteen and forty-five years, the loss of life in that city alone from tuberculosis amounts to the startling sum of \$23,000,000 annually."

It should never be forgotten in a public lecture that much good may be accomplished by a dignified protest against the use of patent medicines and the dangerous and nefarious trade of quacks who advertise "sure consumption cures" alleging some secret method or remedy. A very valuable pamphlet has been issued by our Tuberculosis Committee and the New York Department of Health on so called consumption cures.

I take pleasure in reproducing it here for those who wish to use it for their propaganda.

CONSUMPTION "CURES."

The consumptive is the ideal victim of the quack, charlatan, and vender of patent medicines. Consumptives spend more money on patent medicines and special modes of treatment than any other class of persons who are really ill. The amount of money thus thrown away is almost as great as that obtained from fancied or real sufferers from catarrh or dyspepsia. Every year sees new remedies and methods of treatment advertised, only to be replaced later by others; of treatment advertised, only to be replaced later by others; and almost all these "cures," if well advertised for a time, pay their originators well. All such advertised special "cures" and methods of treatment are practically worthless, and many of them harmful. As Samuel Hopkins Adams says in his article on The Great American Fraud in Collier's Weekly, "Every advertisement of a consumption cure cloaks a swindle."

There are a number of reasons why the consumptive is such an easy prey to quacks and charlatans. Consumption is not a disease of rapid progress as compared to other illnesses; even the cases of "galloping consumption" rarely terminate in less than three months, and the average case of consumption lasts at least two or three years. There is consumption to the consumption that the consumption is the consumption to the consumption to look about him to graph ample time for the consumptive to look about him, to grasp at any straws in the way of assistance. The consumptive is, by a wise provision of Providence, hopeful—and this brings with it credulity. Many consumptives have not the time or money to undergo sanatorium treatment, or to provide themselves with the special diet so often necessary. and naturally lend a willing ear to the assertions of the quack, who promises to cure them rapidly, cheaply, and without keeping them from their work. In consumption there is not the prostration and dulling of the senses that so frequently accompanies other grave diseases. The consumptive has time to realize all that life means, and to desire ever more ardently and keenly to live

Consumptive "cures" may be classified as follows:

I. Patent Cough Medicines. These almost without exception contain either considerable amounts of opium or morphine, or else alcohol. Both drugs are bad for the consumptive; they give only temporary relief and leave him in a worse state than before.

2. Special Remedies for Consumption. These consist

of preparations of vegetable and mineral substances, usually said to be very rare or to be found only in distant parts of the world. They are practically without any effect whatsoever as regards curing the disease.

3. Serum Treatment. Based on the remarkable value of antitoxic serum for diphtheria, many sera are advertised to cure consumption. So far no serum having any curative effect has been discovered.

Special Diet. Curative influence is asserted by some of the quacks for special kinds of food—all meat or no meat, beef blood, onions, olives, etc.

5. Electricity, X Rays, Light, and Cabinet Cures. These various methods have no special value in consumption. Some of the frauds allege by their means to render the absorption of specific medicines more rapid and thus more efficacious.

6. Plasters, Poultices, and Other External Applications. While the pain of a tuberculous pleurisy may be relieved by the application of a mustard plaster, yet such procedures have no effect on the disease of the lungs. To produce ulcers of the chest wall by means of blistering plasters ters is a useless, brutal mode of treatment, and to state that the discharge ("corruption") from such ulcers comes from the lungs is a deliberate falsehood, uttered knowingly. Such procedures are harmful, as they exhaust the strength of the patient.

THERE IS NO SPECIFIC TREATMENT FOR CON-SUMPTION. A SUFFICIENT AMOUNT OF PROPER FOOD, WITH PLENTY OF FRESH AIR AND REST, CONSTITUTE THE ESSENTIAL BASIS OF ALL SUCCESSFUL METHODS OF TREATMENT.

Realizing the truth of the above statements, the Committee on the Prevention of Tuberculosis of the Charity Organization Society of the City of New York has passed the following resolutions:

Whereas, It has come to the knowledge of the Committee on the Prevention of Tuberculosis of the Charity Organization Society that many so called specific medicines and special methods of cure for pulmonary tuberculosis have been and are exploited and widely advertised; and

Whereas, In our opinion there is no specific medicine for this disease known and the so called cures and specific and special methods of treatment (by electricity, x rays, electric light treatment, "diet" cures, plasters, serums, etc.) widely advertised in the daily papers are in the opinion of the Committee, without value and do not at all justify the extravagant claims made for them, and serve chiefly to enrich their promoters at the expense of the poor and frequent ignorant or credulous consumptive: therefore

Resolved, That a public announcement be made that it is the unanimous opinion of the members of this Committee that there exists no specific medicine for the treatment of pulmonary tuberculosis, and that no cure can be expected from any kind of advertised medicine or method, but only from a sufficient supply of pure air, nourishing food, needed rest, attention to the hygiene of the skin, and such medication as appears from time to time required, in the judgment of a physician.

The above mentioned Committee is composed of the following physicians and laymen, all of whom are especially interested in the subject of tuberculosis, its prevention and

Such or a similar leaflet should circulate in every community and the names of prominent physicians should be attached to it. I am convinced that such a circular would do much toward convincing the people that all the so called sure and quick consumption cures advertised as such are invariably based on false claims.

To say a few words on the abuse of alcohol, to denounce the idea that it is a valuable preventative in tuberculosis or an estimable means to cure, should be the duty of every physician. In doing so he need not make his lecture a fanatical temperance

talk. Every physician is justified to state that alcohol is no preventative, that the abuse of it predisposes to tuberculosis, and that in this disease alcoholic beverages should be considered medicine and not be taken except by order of the physician.

The lecture itself should, of course, be practical and to the point, avoiding too technical and too scientific expressions. It is not always easy to speak the language of science in the language of the people, but one should strive to use plain, simple words, and make himself well understood. While a dignified and earnest manner will always appeal to an intelligent audience, the lecture should be enlivened with some bright, cheerful suggestions, and an occasional witty remark may find its place. Even the citation of suitable poetry may be à propos, as, for example, the beautiful words of Emerson:

"God lent his creatures light and air, And water open to the skies, Man locks him in a stifling lair, And wonders why his brother dies."

If the lecturer is able to speak extemporaneously, it is always the most appealing and successful way to reach a popular audience. But whether the address is extemporaneous or read from manuscript, it should not exceed three quarters of an hour in length. The remaining quarter of an hour should, whenever possible, be devoted to showing stereopticon views, illustrating devices for the prevention and treatment of tuberculosis; such as sputum cups, reclining chairs, window tents, chair half tents, sleeping tents, sleeping shacks, leantos, sanatoria, and special hospitals.

While even the illustrations of bacilli may be useful and interesting ,it hardly seems wise to show a popular audience reproductions of pathological specimens, such as decayed lungs, etc.

No public lecture on tuberculosis is ever complete or will ever fulfill its mission without an ardent remonstrance against phthisiophobia-that insane, exaggerated fear of the presence of consumptives, as such. The lecturer must have, of course, previously explained the simple measures by which the consumptive may protect others from infection and himself from reinfection, and thus have shown the audience the folly of individual phthisiophobia. In a popular lecture it should be declared emphatically that the clean, conscientious consumptive who takes care of his expectoration is no more a danger to his fellowmen than any healthy citizen, and that he should be treated with the utmost kindness and consideration.

Those who as official authorities or private citizens oppose the establishment of sanatoria and special hospitals for consumptives must be convinced of their error. They should be shown the great educational value of a sanatorium for consumptives and should be told that any patient who has been in a sanatorium, even if only for a few months, must of necessity, on account of the training he will have received, become a hygienic factor in the community to which he may return improved or cured. If this simple assurance does not suffice to convert them from their unjustified prejudice against the establishment of a tuberculosis institution, they should be shown the statistics of this country and Europe, which prove that the mortality from tuberculosis

among the inhabitants of villages and towns where sanatoria for the tuberculous are situated has always been considerably reduced after the establishment of these institutions. The cleanly and sanitary habits prevalent at the institutions involuntarily imitated by the villagers have resulted in diminishing consumption in their own midst. Thus, the well conducted and well equipped sanatorium for consumptives serves not only as an institution to cure, but also as an institution to prevent the spread of consumption. It can even be demonstrated that the prosperity of the community which harbors a sanatorium for the consumptive poor has always been improved thereby. By the cures accomplished in such a sanatorium, wealthy invalids are almost invariably attracted to the locality.

But besides the individual or official fear of the presence of the consumptive on account of his disease, there is another prejudice, based on his alleged different and peculiar mentality (egotism, selfishness, immorality, etc.). People forget that among the consumptive invalids of the past and the present there have been and are some of the best types of man and womanhood, useful, noble, and valuable citizens, humanitarians, scientists, and philanthro-

pists.

Some years ago I had occasion to address a group of physicians and jurists, and chose for my title A Plea for Justice to the Consumptives. preparing the address I had collected a number of opinions of the moral standard and mental attitude of the average consumptive. I received replies to my inquiries from such men as Biggs, Bowditch, Bonney, E. D. Fisher, Flick, Janeway, Klebs, Osler, Otis, Trudeau, and they all concurred in the opinion that the moral and mental state of the average tuberculous patient is equal to that of any well person or patient afflicted with other diseases. Dr. Trudeau, to whom we all look up as the American physician who has, perhaps, the largest individual experience with consumptives of all classes of society and in all stages of the disease, wrote me the following in direct reply to the statement which a physician had made in the medical press' to the effect that in the average consumptive psychasthenia, the loss of self control and the rise of brutal selfishness combined to distort the clearness of the patient's ethical perception:

"I have never noticed any greater tendency to immorality or crime among consumptives than is to be found in the average of the human race, as far as it has come under my observation. On the contrary, I have seen all the finer traits of human nature developed to the fullest extent by the burdens which chronic and fatal illness, often slow in its progress, adds to the sum total of what men and women usually have to endure in life. I have seen certainly more patience, courage, self denial, and unselfish devotion to others in consumptives than I have noticed in the majority of healthy human be-Indeed, the sanatorium work never could have been carried on were it not for the self sacrificing devotion to the suffering of others shown by my associates, the nurses, and even the employees at the sanatorium, most of them having come here

¹Saxe: "Psychical Relation of Tuberculosis in Fact and Fiction." New York Medical Journal, August 1 and 8, 1903. originally because suffering from tuberculous disease. History is full of instances which prove that tuberculosis does not interfere with the development to the highest degree of the intellectual, the moral, and the ethical sides of man's nature."

When one will have read to the audience such beautiful lines as these of Dr. Trudeau, the lecturer may be sure to have the sympathy of his hearers, and a large stride toward overcoming phthisiophobia will have been made. If the lecture, which is to be delivered, has for its purpose to solicit financial help it is well, besides presenting the figures already referred to showing the advantages of treating the patient at the right time and at the right place, to relate one or two personal experiences from the lecturer's own professional life showing the need of timely treatment and timely help.

In conclusion, I should like to give to the public lecturer on tuberculosis one point of advice. I do this as the result of personal or rather painful ex-

perience.

The public press is a most powerful factor and indispensable in our crusade against tuberculosis, and I personally deeply appreciate its invaluable cooperation; but at times there is a tendency among the young reporters to try to find something sensational in the lectures they are sent to report, or they misunderstand the lecturer, and the result is a distortion of the meaning in the printed article of the ideas the lecturer had tried to convey. To guard against this there are two remedies: Either to hand a manuscript or a synopsis of the address to the reporter or to ask the newspaper to submit to you the proof before publication. With these precautions you may avoid erroneous and sensational statements and a good deal of annoyance.

Every lecturer will thank his hearers for the close and careful attention they have given him. even if the attention could have been a little closer. But when lecturing on tuberculosis one should never fail to announce it personally, or have it announced by the chairman, that at the close of the address the lecturer will be glad to answer questions on points which may not have been under-

stood or not made sufficiently clear.

If the lecturer is a physician, he will be almost invariably asked questions as to the best methods to pursue in individual cases, what kind of medicine to take for a certain symptom, and so on. Such questioning is pardonable, because it may be human nature to try on such an occasion to get medical advice for nothing. The lecturing physician will then have to use the necessary tact to avoid answering directly, and will refer the patients to their family physicians, or if they have none, to any physician of their choice.

It is not always a grateful task for a medical man to give a popular lecture, and the public does not always appreciate the time and sacrifice it involves to the busy practitioner. Some people may even be so ungracious as to consider it a means of advertising. All this one must forget and find his reward in the feeling that he has done his duty. lived up to his calling, and been a true doctor—which means a teacher.

16 WEST NINETY-FIFTH STREET.

THE EXPECTANT TREATMENT OF PULMONARY TUBERCULOSIS-A CONTRIBUTION FROM ORTHOPÆDIC SURGERY.*

By Adoniram B. Judson, M. D., New York.

A letter from an old schoolmate reads as follows: "I know of only two, yourself and Keen, of our class (Brown University, 1859), who have advanced our knowledge of the processes of repair of human organisms. The rest of us have tried to keep up with the procession, but have added noth-" The Keen referred to is Dr. W. W. Keen, of Philadelphia. The writer of the letter, Dr. Charles H. Perry, of Worcester, Mass., gave me a great compliment in placing my name with that of the renowned surgeon. Perry never lost the frank and generous impulses which endeared him to his classmates. He was eminent among the practitioners of New England, men who daily add lustre to our profession, modestly unconscious of the fact that a good physician occupies about the most honorable position attainable by any one. On the other hand, the pardonable ambition to add to the sum of medical knowledge leads to questionable ground. It gives entrance to the fairyland of giants and giant killers, where it is hard to tell the real from the unreal, the substance from the shadow. There are many seekers for buried treasure in this enchanted field, but the credit of having found a true gem comes, if at all, at the caprice of rare good fortune, or perchance as an immaterial post mortem decoration. Each new fact appears first as a novelty in the mind of some dreamer, but fails to be appreciated till other related, and belated, discoveries, in other departments perhaps, concur to give to it recognition and potency. Imagination walks ever in front of the advancing line of the arts and sciences, and no member of the band may move forward except in company with the rest. Furthermore, concurrent conditions must be awaited in vogue, habits of thought, and the customs of the country. An illustration is found in the fascinating story of the mosquito fevers. Before our time suspicious glances had doubtless been cast on the mosquito, and the necessity of sequestration had probably been proved by unrecorded experiments before it was demonstrated by Finlay, whose findings were confirmed at heroic sacrifice and supplemented with scientific exactness. It remains for sanitary authority to enlarge its powers at the bidding of new public opinion and complete a great achievement of preventive medicine.

Responding to the courtesy of the president of the section, Dr. Jacobi, I venture to propose a contribution to the discussions of the congress as follows: Patients affected with tuberculosis of the lungs will recover without treatment if the environment is favorable, an extension of the doctrine derived from the study of orthopædic cases that tuberculosis in the joints owes its destructive character to unfavorable environment and not to an inexorable disposition of its own.

Aside from whatever infective quality it may

have, tuberculosis of the joints, the worthy rival of infantile paralysis in the production of lameness, is clinically the expression of a conflict between destructive and reparative forces. After a period of advance the disease retreats. The cause and method of this benign change are not understood, but the surgeon, encouraged by the certainty of its coming, invites its approach by mechanically protecting the affected part, and providing the best possible general environment. This he will continue to do till the nature of the trouble is understood. When knowledge of the tuberculous process leads to its arrest and prevention a portentous medical riddle will be solved.

In all sections of the congress pulmonary tuberculosis will be very much in the minds of our colleagues as the chief burden of their professional lives. In the wide range of general medicine it stands out in baleful perspective. The same distinction is held in the limited field of orthopædic

surgery by hip disease.

"Satan exalted sat, by merit raised

To that bad eminence.

If nothing can be done to promote recovery from hip disease except to correct environment, it will be but a step further to say the same of pulmonary tuberculosis.

The tuberculous hip has been intractable to all forms of positive treatment. Medication has not been neglected. New devices of minor surgery are constantly in the stage of experimentation. New mechanical methods have been counted by the hundreds, and operative surgery has been pushed to the extreme. Although patients have, almost without exception, recovered, curative treatment has not been found, and the often disappointed observer, led by reason and experience, relies confidently on expectant treatment. He provides a local environment which frees the affected part from disturbance, and a general environment which includes abundant food, innocuous occupation, and sanitary housing. The patient is thus assured of recovery with the least inconvenience and the best result allowed by the nature of the case.

Can pulmonary tuberculosis be viewed in the same therapeutical light? It may be said that as one is fatal and the other not fatal, recovery from both cannot be expected to follow the same treatment. Sir Benjamin Brodie said: "Why should hip disease be dangerous? The hip is not a vital organ," and Dr. Henry G. Davis, the leader of the modern renaissance of orthopædic surgery, wrote: "Medical men are convinced that when consumption has once taken possession, it goes not out until the spark of life goes with it." The parts affected have, however, peculiarities of anatomy and physiology which make it reasonable to believe that the treatment accorded to one may be applied, mutatis mutandis, to the other. The lung is a semide-tached, almost pedunculated organ. The hip is an inherent part, interlocked with other parts of the body by far reaching and rigid processes. The construction of the lung is simple, that of the hip complex and jointed. Lung tissue is soft and homo-

^{&#}x27;Read at the International Congress on Tuberculosis, Washington, U. S. A., October 2, 1908.

^{**}Conservative Surgery, 1866, p. 284. Reprint from the same, The (unability of Fulmonary Consumption, p. 4. The views, except in their optimism, have little in common with those here presented.

geneous, completing development with the cry of the new born, while the tissues of the hip range from hardest bone to impalpable synovial membrane, and reach development in late adolescence. The vascular net work of the lung invites infection and encourages repair, while the hip, with its comparatively deficient circulation, reluctantly yields to disease and reacts so slowly that a typical case of hip disease covers several years. If the hip rises superior to tuberculous infection, what forbids the expectation of signal recovery in the lung, so separate from the rest of the body, so simple in construction, with rapidly developing, homogeneous, and plastic tissue, so infused with vascularity, and altogether so alert and responsive to the appeals of disease and recovery? And the factor of safety is to be considered. If both lungs were seriously impaired the case would be fatal, but when it is known that with only part of a lung life may be indefi-nitely prolonged who can put a limit to recovery in a favorable environment

It will be in order to note the environments required in hip disease and pulmonary tuberculosis respectively. A therapeutic precept followed alike by Nature and art is the arrest of the function of an inflamed organ. This is especially applicable to the hip, endowed with wide and active motion, and no less applicable to the lungs, which are in constant motion. The arrest of motion which is sought in the tuberculous hip by fixation may be sought in the tuberculous lung by the omission of exercises that unduly quicken the breath and circulation and by keeping respiration at the minimum, such as is seen in healthy sleep. The possible volume of respired air is a provision for emergencies, but not necessary for health and recovery from disease. It is an unanimous opinion that the seat of inflammatory action must be protected from violent disturbance. This protection is sought in the hip by recumbency or the use of portable apparatus, and may be sought in the diseased lung by the cessation of coughing.

The interesting question arises whether coughing can be arrested or prevented. The impulse comes from a congested point, where an adhesive exudation promptly appears. Coughing destroys this protection and a semifluid secretion soon calls for renewed efforts attended by temporary and doubtful relief and certain injury to membranes in a state of subacute inflammation liable to become chronic. Coughing increases the irritation, and the irritation in turn increases the cough. This is a vicious circle and certainly calls for the intervention of reason and self control. That the lungs are exposed to the risk of injury is clear on a consideration of the mechanics of this muscular convulsion. thoracic and abdominal muscles act on occasion as expulsive organs, and when they respond to an impulse to cough their great power is displayed in severe compression, alternating with sudden release and agitation of the whole respiratory apparatus, while the compressed air driven through the tubes recalls the action of a steam pencil, wanting only the mordant agent to become an excoriating sand

It may not be doubted that intelligent effort will abate this habit and in many cases lead to its cessa-

tion. It is not easy to ignore laryngeal irritations and temptations to cough and to give up what one has been accustomed to for years. Reform is a tedious process, because it takes longer to go up hill than down. Neither is it altogether frivolous to say that if you do not cough the first time you do not have any cough. Expectoration, when unavoidable, may be facilitated by assuming for a moment an attitude in which the direction of the air passage is changed from the vertical to a downward inclination, when gravitation and a little effort provide a harmless exit. In such straits quadrupeds have an advantage with their inclined windpipes, as was seen during the epizootic which visited American horses in 1872.

The local treatment of pulmonary tuberculosis, based on the teaching of orthopædic practice, may be outlined as follows: I, The omission of whatever unduly excites respiration and circulation; 2, the habitual reduction of the volume of respired air to the minimum; and, 3, the inhibition of coughing.

Turning now from local to general considerations, it is evident that a favorable general environment should be equally accorded to the hip patient and the consumptive, and, indeed, in view of prevention, to every member of the community. The question of how to distribute evenly the advantages of abundant food, innocuous occupation, and sanitary housing is calling aloud for quick attention.

In passing, I suggest the possibility of relaxing the custom which regulates the hours of taking food. Is it wise to eat three meals at short intervals and then give a long interval to fasting? An old custom of the navy called for the "meal pennant" at 8 bells. Thus the men had breakfast at 8 o'clock, dinner at 12, and supper at 4. Three meals within eight hours were followed by a fast of sixteen hours. The efficiency of the ship's company may not have been appreciably reduced, but an even distribution and the omission of fasting would have agreeably modified the dietary. In this connection the method of the machinist when he gives fuel to his engine may be recalled, and the rules which govern feeding in the nursery and the typhoid ward.

It has been said that prevailing east wind and atmospheric moisture are less potent as factors of pulmonary tuberculosis than parsimony. Tuberculosis of the joints is especially a menace to childhood, and yet in this period, when the vital processes are at their best, and growth and development are active, it would seem that natural resistance to general disease should be alert and give protection from dangers of this kind. In early youth the circulation is rapid and full. are not easily deprived of their share of respira-tory activity. They are not given to introspection and melancholy, which have been thought to favor the approach of general or constitutional diseases. Their habits are far from sedentary. Their minds are free from worry and their bodies from overwork and long hours without rest and recreation. By this process of exclusion their danger may perhaps be traced to some mismanagement of alimentation. Some unfortunates are, from sad necessity; denied sufficient food. Others, perhaps, suffer be-

cause prudent economy finds easy expression in a scanty allowance to the younger members of the family, reinforced by a common and not altogether unreasonable idea that it is bad for a child to eat Overeating may, of course, induce acute disorders of brief duration, but, on the other hand, prudence of this kind may easily lead to the more serious mistake of opening the door for chronic affections by withholding sufficient nourishment. Certain young parents who have no reason for economy seem to have an idea that the precious object entrusted to their possession has delicate and sublimated qualities which, for a time at least, exempt it from the common necessity of an abundance of good food.

Without experience in diseases of the lungs, I am not so presumptuous as to assert too much for the therapeutical concept included in this paper, but logical inferences may prove to be practicable and useful, and the argument here ventured will not be in vain if it throws a single ray of light on a most

important subject.

The prevention of disease is what gives to the physician the greatest pride and delight. Next to that comes the satisfaction of recognizing and providing for the miracle of recovery by the expectant treatment. It may be asked what will be the status of the medical profession when prevention and expectation shall have reached the beneficent extremes so eagerly anticipated. The medical student, if he has time to read these remarks on pulmonary tuberculosis, will say, "But where does the physician come in?" My young friend, he is not coming in. His successor, say fifty years from now, may be the trained nurse, coming in with cap and froufrou. The physician (Dr. Sine Qua Non) may then be found in the State laboratory, making a diagnosis, or perchance prescribing absent treatment for the Martians.

53 WASHINGTON SQUARE.

FAMILY TUBERCULOSIS.

A Unique History and Some Suggestions.

BY WILLIAM CHARLES WHITE, M. D., Pittsburgh,

Medical Director, Tuberculosis League.

The family of Y lived in X, a small town of ten thousand people in the highest part of Ontario. They were always in good circumstances and lived in a most hygienic way as regards food, rest, cleanliness, and sanitation. They always lived in new houses from the time of the parental marriage until the time of the present history.

In 1908, when this history was written, the family consisted of father, mother, and seven children. The ages were as follows: Father seventy-one, mother fifty-nine, A thirty-eight, B thirty-six, C thirty-four, D thirty-two, E twenty-nine, F twenty-seven, and G twenty-one.

The father was a chemist and druggist up until ten years ago when he retired, and was always in fair health. The mother was always in good health. They lived in X in an excellent home under the best conditions. A was an electrical engineer, married with three children and lived in T, a city of two hundred and fifty thousand in-habitants. B was single and taught school under delightnationalists. Be was single and taught school in a suburban district in New York state. C was a physician, married with two children, living in J, a city of one hundred and fifty thousand inhabitants. D had university education, was married, had four children, and lived in T, a city of two undered and the thousand mind rents. E was a trained nurse. F lived at home with the parents in a most healthful way. G was at the University of M, a city of five hun-

dred thousand inhabitants.

The history of the family of the father of the family of Y is as follows: His parents were always healthy and died of old age. His three brothers died of tuberculosis. They died some years after their marriage and after the father of the family of Y was married, but never lived in the house with the family of Y, and died before the birth of the four youngest children of the family of Y. He had two sisters living who had always been well, aged sixty-five and sixty-eight. He had one sister also who died in childhood by accident.

childhood by accident.

The history of the family of the mother of the family of Y is as follows: Her father died of old age. Her mother died at thirty-two, of pneumonia (probably due to the pneumococcus, judging by the history). One brother was living and well; one sister died in childbirth, but always had good health up to the time of her death.

So far as the writer could determine, the members of the family of Y were never exposed to direct infection, even remotely, from human source. They lived together up to 1892, when the oldest child left for college. The next year the second child left for college, and in 1894 the third child went to the university. From this time on the family were never all living continuously together. The older children, after their university course, started their lives in different distant places, and the younger children kept replacing them at school: They all remained in comparatively good health until 1907, when the following most remarkable series of events occurred.

C, the physician, who lived in a city of two hundred thousand inhabitants in the middle western States, and who had not lived at home for ten years, began to raise a little morning plug of sputum which, upon examination, be found to contain tubercle bacilli. No lesion could be found to contain tupercle backing. No lesson could be found in the chest at this time by expert examiners, among whom was Dr. William Osler. He, however, repaired to a resort to take the cure, where later right and left apical lesions became evident. His wife, who was the daughter of two who succumbed to tuberculosis in her youth, and his two children were at this time and have continued in perfect health. In the family of Y, C was at this time

periodably under the severest strain of overwork and worry. Five months later, while C was at the parental home in X, E, the fifth child, age twenty-nine, returned from her nurse's training. C noticed her afternoon tiredness and face flushing, and while there was neither cough nor sputace nusning, and white there was notated turn, he found upon examination, a well marked right apical lesion extending as low as the second interspace in front and the spine of the scapula behind. The afterin front and the spine of the scapula behind. The after-noon temperature in this case was 99.4° F. to 100.2° F daily for some months from this time onward, and a month after this time she gave a most violent reaction to 2 mil-ligrammes of old tuberculin. E had been under very severe strain in charge of the operating room in one of

Eight months later the father, age seventy-one, living most comfortably in the home at X, had what was called most contortably in the nome at A, had what was called a severe cold, coming on rather abruptly with fever and chills. This did not improve, and two months later it was found to be tuberculosis, the lesion involving the upper half of the right lung. The sputum, when the nature of the process was discovered, was about one ounce daily, and tubercle bacilli present in large numbers. About the same time A, the oldest child, was complaining of illhealth and was found to have a right apical lesion which was evidently active. He felt he could not give up his work at this time and a few weeks later he was prostrated with a lower right lobe pneumonic attack. Apparently the in-

a lower right lobe pneumonic attack. Apparently the in-fecting organism in this was a streptococcus. No tubercle bacilli were found in the sputum, but doubtless from the slow process and the continued fever after the pneumonia had cleared with increased right apical activity, the tuber culous process was in the main responsible. No tuberculin was given in this case, and his medical attendance was not such as to justify reliance. The diagnosis was made by

the largest American hospitals.

such as to justify reliance. The diagnosis was made by the writer who saw the patient three times.

About the same time as A's and the father's trouble, B was found to have advanced tuberculosis, from which she had doubtless been giving evidence in morning sputum, cough, and elevation of evening temperature for a year. When diagnosticated the sputum was an ounce in

quantity, and bacilli present in numbers to correspond to a Gaffky count of six, and the upper and lower lobes on both sides involved. This case is a sad comment upon the medical profession's carelessness. B had been under the care of prominent New York physicians; had had her appendix removed in Johns Hopkins Hospital, Baltimore; had been treated in England, Ireland, and France for intestinal disorders by men recommended as the best in their localities, all within a year's time; with the most reprehensible lack of thoroughness, they with one accordicated to her tale of abdominal discomfort and neglected every other part of her body. Her intestinal and appendicular trouble, into which I have carefully inquired, were doubtless either tuberculous, for she had tubercle bacillis in her stools, or due to the toxine of the tubercle bacillis in her stools, or due to the toxine of the tubercle bacillis in her stools, or due to the toxine of the tubercle bacillis in her stools, or due to the toxine of the tubercle bacillis in her stools, or due to the toxine of the tubercle bacillis in her stools, or due to the toxine of the tubercle bacillis in her stools, or due to the toxine of the tubercle bacillis in her stools, or due to the toxine of the tubercle bacillis in her stools, or due to the toxine of the tubercle bacillis in her stools, or due to the toxine of the tubercle bacillis in her stools, or due to the toxine of the tubercle bacillis in her stools, or due to the toxine of the tubercle bacillis in her stools, or due to the toxine of the tubercle bacillis in her stools, or due to the toxine of the tubercle bacillis in her stools, or due to the toxine of the tubercle bacillis in her stools, or due to the same time or due to the same

About the same time G received a slight injury in football and soon after complained of pain in the right side. He was found to have a pleurisy which developed an effusion in which tubercle bacilli were found. Upon examination he also had an incipient right apical lesions in

both upper and lower lobe

There were still three left in the family, mother and two daughters. The two daughters were both complaining about the same time of afternoon tiredness and morning sputtum, and marked intestinal disturbance. F had just finished a period of two months' rest cure in the open air in a sanatorium for her intestinal difficulty, and had made good recovery. This intestinal trouble, I am positive, was due to a tuberculous lesion in her right apex (upper) and her left lower apex. These were both active when the writer saw her upon her return home, when the father took sick. D was also found at the time to have a lesion at the right apex which explained her rapid decline in weight and health, and her other symptoms. The mother alone escaped the infection.

This is a mere outline of the facts in this case of family tuberculosis. To recapitulate: There developed in fifteen months eight cases of tuberculosis in a family of nine who had not lived together for ten years, who were scattered in six different homes in five different American and Canadian cities. The ages of the victims ranged from seventy-one to twenty years. There was no known source of infection; they had always lived under the best conditions. Four were diagnosticated by the presence of tubercle bacilli, one by tuberculin, and three by physical signs and symptoms. The writer made or confirmed the diagnosis in every case.

Some striking features in the history, symptoms, and examinations here merit special mention. The members of the family were brought up on milk without other beverage save water until they left home. The father consumed large quantities of cream. The mother, who escaped, took very little milk, no cream save in her tea, and very little butter. About the time the family ceased to live together they moved into a new house, and the source

of milk was shortly after changed.

The symptoms of intestinal distress were common to all patients. They were so marked in two cases that the appendix was removed from each under the supposition that this was at fault. All the cases were apparently of good resistance against the infection, because, upon assuming what is now taught as the proper method of combating this infection, they made good recovery. The tubercle bacilli were in the four cases in which they were found of similar morphological structure, that conforming to the bovine type as described by Weber and others. Short, thick forms, irregular in outline. These preparations the writer has examined repeatedly, personally, and the resemblance is very striking. Unfortunately the opportunity for the

isolation of the organism in all of the cases save one is past. This isolation is being attempted at the present time in the one case with the desire to apply to it the Theobald Smith reaction test.

A striking coincidence is that a family of four children, who lived not many doors away from the family of Y twenty years ago, when the children of the latter family were young, were two years ago wiped out in two years' time by tuberculosis. They undoubtedly had the same milk supply, but their cases were undiagnosticated until very late.

Most careful inquiry failed to reveal any source of infection of human origin. I repeat this that its significance may not be forgotten. The paternal brothers are, I think, not a factor. They never lived with or near the family of Y; they took sick after Y was married. This, then, makes it necessary to explain the facts in either of the following ways: All were infected individually in their different spheres of life in such a way as to render possible the malady making itself evident in each at approximately the same period of time. With the ubiquitous presence of the tubercle bacilli, this, of course, is possible, but when one considers that this involves the acceptance also of a complete uniformity of relation between the resistance of each individual and his special dose of tubercle bacilli to time the concomitant downfall of all, it is obviously an untenable statement.

Far more likely is the other possibility that all were infected with approximately equal doses at approximately the same time from some source other than human. This allows the difference in the chemical resisting powers of the individuals caused by innate and extraneous factors, such as work and worry, to explain the paltry differences in the time of the appearance of the malady in each case.

Such a view is strengthened by the bovine morphology of the infecting organism in those cases in which it was found, by the habit of the family in consuming large quantities of milk, and by the escape of the only one who used very little milk; which facts also go to prove that the source of in-

fection was bovine.

The recital of this instance of family infection is, if viewed in this way, corroborative evidence of the von Behring view. And, in accord with the findings of the present day authorities in this and foreign countries, it also constitutes a plea for a more rigid crusade on the part of our organizations for the "prevention of tuberculosis" against the disease transferred from cattle to man. Those who labor in this field of work cannot but be struck with the small decrease in the amount of tuberculosis in certain centres as compared with the labor and money expended. Mr. E. G. Pope, whose recent sad death at Saranac Lake removed a life hard to be replaced, showed me shortly before his death certain charts based upon the death rate from tuberculosis in various countries for the past fifty years. These demonstrated that in the first twentyfive years of the half century the decline in death rate from tuberculosis was quite as great and in some countries greater than in the last twenty-five, or, in other words, greater in the quarter century

preceding the discovery of the tubercle bacillus than in the quarter century following this dis-

This same fact has lately been shown in a striking way by the figures published by S. T. Maher for Connecticut, Medical Record, August 1, 1908. Even more striking are the lessons from the figures of B. Fränkel for Germany. One hundred and thirty-five sanatoria for adults, 18,927 beds for consumptives, 270 dispensaries and places for educational purposes, and only a reduction in twenty years of 13.88 per 10,000 in the mortality. Something must be at fault.

Another pertinent question to be decided and one that grows in importance the more it is considered, is whether the mortality from tuberculosis and the decrease in the same, is a correct indication of the incidence of tuberculosis. It seems to me we fail often to see that our ability to prolong life explains often in great part the decrease in mortality rate, to wit, the German figures, twenty per cent. only of those treated are dead five years after the treatment. The important figures would be those indicating the number of new cases arising annually, and on these figures only would we be fully justified in reckoning the true efficiency of our work. Those who are working in the tuberculosis field must be struck with the fact that the supply keeps up.

The study of this family has stimulated the suggestion that we too often, perhaps, neglect the questions of dosage of bacilli in tuberculosis and the following incubation period. I am not prepared to lay down any law governing these points, but at the present time I feel convinced that the progress of any case of tuberculosis depends more upon the number of bacilli received within a given period than upon any other one factor. The varying dosage in different cases may lead to immunity or to any condition of tuberculosis from acute miliary to chronic fibroid phthisis. Probably the reason we have so little tuberculosis, since every one is exposed, is that the dosage is fortunately such in amount and spacing in the majority of individuals as to lead to a more stable immunity.

BEDFORD AVENUE AND WANDLESS STREET.

REPORT OF SIX MONTHS' WORK IN THE BROOK-LYN HOSPITAL DISPENSARY, FIRST SURGICAL DIVISION,

Including a Brief Report of Five Hundred Cases. BY J. EDDY BLAKE, M. D., Brooklyn, N. Y.

V. a. b. Sarada, Bradda, Traptal Domany; Instructor in Sages, New York, Peage data's School, Physician to the Brooklyn Methodist Episcopal Home.

Progress comes by trial and comparison. And, especially in our profession, we need always to test the new by the old; and in our enthusiasm for the new, never to lose sight of the old, until experience has demonstrated that the new is really better. If this precept were only more regularly followed we would less frequently see new drugs and new measures, at first exploited as cure alls, only later to be unequivocally condemned as worthless or injurious. A notable example of this tendency first to overestimate and then to underestimate the value of a new medical discovery is presented in the rise and fall in popularity of the coal tar antipyretics.

In order to determine the relative value of our various methods of treatment, a frequent comparison of results is necessary. And with this idea in mind, I have reviewed the histories of the last five hundred cases treated in the Brooklyn Hospital Dispensary, first surgical division. I shall not burden you with statistics, but will endeavor to present for your consideration some of the more interesting

facts derived from their study.

At the outset, it should be stated that our records are incomplete, and often unsatisfactory. Many of our cases, perhaps a majority, cease coming when almost well; these are usually classified as cured, although healing was not quite complete when last seen. Many others fail to return after one or more treatments, and we have no information as to the final outcome; these are usually classified as improved, but most of them recover speedily, with or without further attention. Fractures and sprains are classified as cured, even though a certain amount of disability remain when they pass from under our care. And wounds of fingers and toes or amputations are classed as cured when the wound heals, even though there was loss of substance.

It would be impossible with our sized staff to keep a detailed history of every case treated; and hence the reports of some of our cases are very meagre. And yet, in spite of all the omissions and imperfections in the data, and allowing for the difficulties and possibilities of error in compilation, our study has revealed much of interest and value.

The cases may be grouped in three general classes. First, those simply examined and referred to the hospital or to some other clinic; these were comparatively few in number, and are of no significance in our study. Second, those referred to us from the hospital, to treat during the terminal stage of their convalescence after operation or injury; these were likewise comparatively few in number, but include many of the severer injuries noted in our list. As a general rule, cases of extensive burns, fractures or dislocations of the lower extremity, dangerous injuries to the head or trunk, etc., are usually provisionally dressed by the ambulance surgeon and treated in the hospital. If seen by us at all, it is only after convalescence is well established. Many of these cases fail to heal promptly, and require treatment for long periods of time. The third class includes the remainder of the cases. Of these, a considerable proportion, especially those suffering from injury, had likewise been dressed one or more times before coming under our care.

As a general rule, most of the cases do not require more than one or two weeks' treatment. But there is a minority of cases, of old ulcers, sinuses, tuberculous disease, fractures, etc., in which treatment may be necessary for months or years. Such cases, however, usually make the rounds of the dispensaries, and fail to remain under the care of any one, until a cure could be effected when that is pos-

[&]quot;Read at a receiver of the Bendeva, Hopatal Club, November

As might be expected in a surgical clinic, wounds were more numerous than any other class of cases. They numbered 135, or twenty-seven per cent. of all the cases seen. Not quite one third were incised wounds, and slightly more than two thirds were lacerated. The lacerations, however, were in most cases trivial. One sixth of the incised wounds and one twelfth of the lacerated wounds are recorded as infected. Infection was actually present more frequently than this, but in many cases it was too slight to be noted on the record. Contrary to expectation, the incised wounds appear to have been infected about twice as often as the lacerated. This is apparently due to the fact that the slighter injuries are more often neglected until infection has become marked, whereas the severer injuries are presented for treatment before infection has occurred, or at least before it has made appreciable progress. The incised wounds were distributed in about equal numbers among the four following localities: Fingers, hands, face, and remainder of the body. Of the lacerated wounds, about one third affected the fingers, one quarter the face, one quarter the scalp, and the remainder other parts of the body. In addition to these we treated six cases of canine bites, two of human bites, and three of poisoned insect stings. Furthermore, we treated forty-eight cases of infection in which no primary wound was discoverable, or in which it was trivial or had healed. Of the later cases, three quarters affected the forearm, hand, and fingers, and the remainder the face, neck, and lower extremities. Most of our cases of punctured wounds belonged to this class, and the remainder are grouped with the incised wounds.

Suppurating nontuberculous glands needed incision in eleven cases; boils in five; and abscess of

the breast in two.

Twelve cases of abrasions were treated, and twenty-eight of contusions. In one of the latter cases a large hæmatoma of the thigh developed, which promptly subsided after aspiration.

Burns, mostly of the hand, furnished twenty-one cases! Six of these were Fourth of July burns, and three were electric. None were very severe or ex-

tensive.

Sprains were met in seventeen cases; seven of the ankle, five of the knee, three of the wrist, and

one each of the shoulder and phalanges.

Dislocations were only treated five times: Two of the shoulder, respectively one subcoracoid and one subglenoid; one of the elbow, which was reduced by the patient before he arrived at the clinic; and one each of the thumb and forefinger.

Fractures were present in twenty-five cases, as follows: Six of the wrist (Colles's fracture), four of the ribs, three of the phalanges, two each of the metacarpal and metatarsal bones, and one each of the zygomatic arch, external condyle of the humerus, clavicle, Pott's fracture of the ankle, ulna, radius and ulna, nasal bones, and fourth cervical vertebra.

Eleven cases of tumor presented themselves for treatment. Four sebaceous cysts of the scalp and one dermoid cyst of the face were removed. One nævus and two epitheliomata of the face, one recurrent sarcoma of the jaw, one recurrent sarcoma of

the cervical glands, and one sarcoma of the tonsil were referred to the hospital for operation.

Of skin lesions, eczema was the condition for which relief was most commonly sought; we treated eleven cases. Scabies came next with four cases. Inpetigo contagiosa, erysipelas, and trichophytosis each furnished two cases; ivy poisoning three cases, and urticaria, sycosis, and lupus one case each.

Foreign bodies were removed in eight cases; namely, splinters from the fingers three times, and from the arm once; a fish hook and a needle from a finger once each; an encysted fragment of glass from the wrist; and a button from the ear.

Ulcers of the leg were treated in twenty-three cases. Of these, five were traumatic, five syphilitic, ten varicose, and in three the cause was not deter-

nined.

Twenty cases of tuberculous infection were treated. Of these, two were of the wrist, one of the flexor tendon sheaths, and one of the skin of the forearm, one each of the shoulder, tibia, knee, and prostate, and twelve of the cervical lymph glands. Several of the latter were complicated by axillary adenitis and tuberculous deposits in the lungs.

Phimosis was noted in seven cases, and paraphimosis in two. Two cases of anterior poliomyelitis were examined and referred to another department for treatment. Six patients sought relief for painful scars, eight for old sinuses, and four each for hæmorrhoids and ingrowing toenails.

The remaining sixty cases presented nearly as many different lesions. And my time and your patience would hardly suffice to mention them in detail

Having thus briefly summarized the various classes of cases coming under our care, let us now consider some of the more interesting details relat-

ing to their treatment.

Fresh wounds are usually treated with dry dressings except when very dirty, very ragged, or when punctured. The amount of preliminary cleansing of the neighboring skin depends upon circumstances. If not very dirty, it is simply sponged off with Thiersch solution; but if necessary, soap and water, oil of turpentine, and ether are used to remove the grime, and then the parts sponged off with the Thiersch solution. As a rule, no attempt is made to disinfect the wound itself. But care is taken to remove any foreign particles, and in the case of lacerated wounds to remove disorganized tissue. But even in these latter cases we are very conservative; and it is often surprising to see what brilliant results may be achieved with conservative treatment.

Sutures are sometimes necessary to retain parts in correct apposition. But very frequently sterile adhesive strips are used instead of sutures, and have proved very satisfactory. Of course they can only replace superficial sutures, and be used with

dry dressings.

Aristol powder is generally used on clean incised wounds, but has not proved satisfactory on others. For denudation of skin, boric acid ointment or silver foil are usually employed. For abrasions with slight infection a ten per cent. ichthyol ointment usually proves very satisfactory. Fresh lacerated wounds after the preliminary cleansing, are generally put up in balsam of Peru. This mechanically entangles

bacteria, and by its mildly antiseptic action, prolonged for hours, prevents their growth. At the same time it is chemotactic and stimulates granulations. It is worse than useless, unless it can come in contact with all parts of the wound, and unless it is used before the bacteria have gained access and begun to multiply in the deeper tissues. If the wound is too dirty, or if infection has become appreciable, wet dressings should be used instead. Furthermore, Peru balsam seems to be of value only for two or three dressings. After that, something else should be substituted, even though the balsam is used again at a later stage to stimulate granulations. When granulation is well advanced, bismuth subiodide is frequently employed to stimulate the growth of epithelium. If the granulations are too exuberant, silver nitrate may be necessary to control them. Strapping often has a most beneficial effect in promoting the growth of epithelium, and so also the placing of a small piece of glass over the granulating area. Boric acid and zinc oxide ointments are frequently used in the later stage of healing.

Infected wounds, and infections without a visible wound, are generally treated with wet dressings. Frequently incision is indicated to relieve tension and provide drainage; but in some of the milder infections, lymphangeitis, etc., suppuration can often be prevented and incision rendered unnecessary by

the use of wet dressings alone.

I have noted that wet dressings are used far more commonly than a few years ago, when I was a hospital interne. Now practically all of our serious and many of our mild infections are thus treated.

The choice of solution to be employed depends on various considerations; the site and extent of the infected area and the character of the infection; the intelligence of the patient; and the personal preference of the surgeon in charge of the case. Although carbolic acid is tabooed in most clinics, on account of its supposed dangers to life and limb, I very frequently employ it with the happiest results. For severe and moderate infections about the extremities, a phenolboric acid solution controls the pain and checks infection as no other solution does; and if properly used it is not dangerous, all statements

to the contrary notwithstanding. A recent article by Meyer quotes numerous authors and gives the impression that the use of phenol in weak solution is liable to be attended by untoward consequences. But an analysis of the reported cases shows that the strength of the solution, when known, always exceeded two per cent.; and every one should know that this is too strong to be used as a routine procedure, especially on fingers. In this conection, allow me to call to your attention a popular fallacy, which I have found to be common among physicians; namely, that a teaspoonful of drug to a cup of water makes a two per cent. solution. The ordinary coffee cup or glass filled to the brim contains about eight ounces; the teacup somewhat less; and filled to within one half or three quarters of an inch of the top, as is customary, a "cup" contains about six to seven ounces. Furthermore, an ordinary teaspoon holds considerably more than a drachm, on an average about a drachm and a half. Hence, the careless doctor who prescribes a teaspoonful of pure phenol in a cup of water, supposing that he has ordered a two per cent. solution, may be surprised by a bad burn or gangrene of a finger. But a careful investigation would reveal the fact that the patient, following the doctor's directions, had used in reality a three or even four per cent. solution, which is sufficient to cause gangrene in most any case, if used long enough. Furthermore, it should be remembered that pure phenol is only slowly soluble in cold water; and unless care is used, much of the phenol may remain in globules undissolved on the bottom of the vessel, instead of being diffused evenly through the solution. Lack of care in seeing that the phenol was entirely dissolved has often resulted in severe burns, damaging both to the patient and doctor. In order to increase the solubility of the phenol, it is advisable always to use a mixture of phenol and glycerin, equal parts. Still further, phenol should not be used over very large areas, on account of its ready absorption and the danger of toxic symptoms. If the urine turns smoky or greenish black, the doctor should know that too much absorption is taking place; and unless he does know it, no doctor should employ this agent.

But limited to its own proper field, especially infections in the tendon sheaths, and in the deeper tissues of the extremities, there is no other remedy with which I am familiar that so speedily relieves pain and checks a spreading infection. A two per cent. solution is sometimes recommended, but this I consider risky, especially in children and where the circulation is poor. A one per cent. solution is strong enough and not risky. I usually order the

following prescription:

 B
 Phenol,
 .2 grammes;

 Glycerin,
 .2 grammes,

 Boric acid,
 .4 grammes;

 Water,
 .200 c.c.

The addition of the boric acid appears to increase the efficiency of the solution. If I fear this amount will prove insufficient, I double the quantity, or I double the strength of the solution, and order that it be diluted with an equal quantity of water before use. Occasionally, if the skin is very delicate or if the circulation is very poor, or if the area to be kept wet is large, I may order but one gramme of phenol to the 200 c.c.; but this is rather too weak for routine use. Where the infection is severe but limited, as in a small abscess, we often use the ninetyfive per cent, carbolic acid solution to destroy the site of the infection. We swab out the cavity of the abscess first with dry gauze, then with the phenol, and after a minute or two with ninety-five per cent. alcohol. A couple of days after such an application a small abscess will often be nearly well. Boils are often thus treated, the phenol being introduced into the infected hair follicle by a sharpened toothpick or match, on which are wrapped a few fibres of cotton. When the ninety-five per cent. phenol solution is used, the skin should be well greased, and care be taken even then not to spatter the acid around; for if carelessly used it may cause severe burns. Water will not stop the burning; alcohol is the antidote.

For severe infections of the extremities covering a considerable area, we generally use a corrosive sublimate solution, one to two or three thousand, prepared with alcohol and water equal parts. This has to be used with care, and the patient watched

for symptoms of mercury toxæmia. For deep infections I do not think it as efficient as the carbolic solution; and it often causes a severe dermatitis, which prevents its continued application. Five per cent. ichthyol solution may be used instead, but its odor and staining properties often render it objectionable to fastidious patients. Burrow's solution acts well with mild lymphangeitis, but is not used for the severer infections.

For the ordinary class of mild infections the Thiersch solution (boric acid, 5 parts; salicylic acid, 1 part; and water, 500 parts) has proved very satisfactory, but it is of little or no use in very severe infections. Of course incision and drainage is often

the first requisite in many of the cases.

After the further progress of the infection has been checked and healing is well advanced, we usually substitute for the wet dressing an ointment dressing of boric acid or ichthyol, ten per cent. As a mild antiseptic and astringent lotion, red wash is sometimes used. And as an escharotic a ten per cent. zinc chloride solution is often employed.

For a number of months past we have been using the Bier treatment in combination with other measures, and in most cases it has seemed to materially hasten convalescence. We have used both the suction cups and elastic constriction on suitable cases, and always with satisfactory results. The great drawback to the use of the suction cups is the amount of time consumed, but for treating localized infections, punctured wounds, sinuses, etc., they are often indispensable. The elastic constriction can be left to the care of fairly intelligent patients or their friends, and after the first application demands but little of the doctor's attention. At the same time the doctor is responsible to a certain extent for the result of treatment, and must see to it that the elastic bandage is properly applied-i. e., tight enough to cause a moderate hyperæmia, but not tight enough to cause pain or even marked discomfort, and certainly not tight enough to cause numbness and coldness in the limb.

Abrasions are usually treated with an ointment, zinc oxide, boric acid, or ichthyol. If considerably infected a Thiersch dressing or a five per cent ichthyol solution is applied. Contusions are treated with rest and support; often with lead and opium

solution or ichthyol ointment.

Old burns are usually treated with boric acid ointment unless markedly infected, when a boric acid solution, or a weak ichthyol solution, is employed. If not too large a very weak phenol-boric acid solution may be employed, but this is rather risky; absorption takes place so easily. The same is true of the carbolic ointment, which is so frequently used for this condition. Fresh burns of any magnitude are usually treated in the hospital; those which we see are usually treated with one of the ointments already mentioned. In a couple of cases a picric acid dressing has given us very satisfactory results, and we intend to continue its use in the future.

Sprains are usually strapped, but for the first dressing lead and opium lotion may be employed. Dislocations and fractures are reduced, and appropriate dressings applied to keep the parts in proper position. In the case of fractures, we usually have the patient return four or five times during the first

ten to fourteen days, and each time the limb is gently massaged and the dressings reapplied. During the following two weeks a permanent splint is worn and the parts left undisturbed. After this a light splint is worn for about two weeks, and removed every couple of days or oftener for massage. Experiment has shown that in the ordinary uncomplicated case bony union begins and is practically completed in the period from the thirteenth to the twenty-fourth day; and that only during this time is absolute fixation desirable. The massage tends to prevent atrophy of the muscles; and by this plan of treatment the best possible result is achieved in a minimum of time.

There being no separate skin clinic connected with the hospital, all such cases are referred to us for treatment. By the use of antiseptic, sedative, or stimulating ointments, solutions, or powders, we have been able to cure all the cases applying for relief. But as our list shows, they were all acute or subacute cases, amenable to treatment. Our most stubborn cases were eczema and lupus; but even

these responded to treatment.

In the treatment of various forms of tuberculosis we have had considerable success. This I believe is to be attributed to the fact that we pay marked attention to treating the patient for tuberculosis, as well as to treating the local lesion. And we give advice as to hygiene and dietetics, as well as apply dressings and prescribe drugs. You may recollect that our late friend and colleague, Dr. Herman, read a paper before this club several years ago on the value of potassium permanganate in local tuberculous lesions. I have continued this line of investigation, and although not prepared to make a detailed report, I can say that I have had marked success in several cases where it was employed. The last patient treated had been operated upon several times for tuberculous disease of the shoulder, and when he came under my care the shoulder was apparently ankylosed, and eight sinuses were discharging great quantities of pus. Now, after about a year of very irregular and intermittent treatment, the sinuses are entirely healed, there has been a considerable increase in the muscular development about the shoulder, and he has regained a fair amount of motion in the joint itself. The cure appears to be absolute; but, of course, it will take years to determine this point. I have had two patients in private practice who have remained well for three years after the cure of a tuberculous ischiorectal abscess and of suppurating glands in the neck and axilla, both complicated with pulmonary involvement.

We have had to treat several cases of malignant tumor, recurrent after operation. We have tried Coley's fluid, amylopsin, trypsin, and extract of thymus gland. In a couple of cases the disease seemed to be held in check for a time and life prolonged, and in others no result was noticeable. So our small experience in this line has not been very encouraging.

In conclusion I would say that the work is interesting and valuable, both to the men in charge and to those treated. In addition, we strive to impart information and opportunities to gather experience to a certain number of students who desire to gain

more knowledge as to the best method of recognizing and treating common complaints than can be gained by didactic lectures. After watching the work done in dispensaries where students are admitted and those where they are not admitted, it is my judgment that their presence is an advantage to all concerned. And I believe that the best results will be achieved when dispensaries and hospitals are correlated to medical schools and serve as institutions for the discovery and dissemination of medical knowledge, as well as for the treatment of those receiving their care.

352 JEFFERSON AVENUE.

INSUFFICIENTIA PYLORI VERSUS EINHORN'S ACHYLIA GASTRICA.

By Mark I. Knapp, M. D., New York.

It is now over six years that my first article on insufficientia pylori has been published, and since then I have added a few more monographs on the same disease. My first writing gave the history of fourteen cases, and my next publication, printed some six months after, added twelve more cases. Since that time the number of cases of insufficientia pylori that I have seen and satisfactorily treated runs into the hundreds. Revolutionary as were the theories expounded by me in my first work, they have now found adherents. Moreover, what at that time was, with me, the result of only logical inference has now actual facts as a base.

Insufficientia pylori expresses the existence of a positive state, and its clinical aspect runs in the same identical rut with achylia gastrica. In other words, what Einhorn described as achylia gastrica my investigations proved to be insufficientia pylori. My substituting the name of insufficientia pylori for the selfsame clinical picture, known as achylia gastrica, was not intended to be merely a play of words. My desire is to teach the exact condition which prevails; and the prevailing condition is not a loss of digestive secretions as denoted by the word achylia, but the prevailing condition is a non closure or an insufficiently tight closure of the pylorus; the digestive secretions are extremely rarely absent in the stomach. This teaching is in marked contrast with the teaching of Einhorn. Either achylia gastrica exists or it does not. My contention is that there is no such thing as achylia gastrica, although there exists atrophy of the mucous membrane. If achylia gastrica exists then such cases have surreptitiously eluded me these many years of my special practice of gastrology.

Achylia gastrica has been described by Einhorn as a condition in which there is either nothing at all in the stomach one hour after the eating of the test breakfast or else there is but a trace of chyme—if chyme it should be called at all—imbedded in mucus. Such cases I have seen, treated, and cured by the score. Only I gave up the name of achylia gastrica soon after my return from Ewald and after I had found that I could make no headway by way of curing my patients. This renouncing of achylia is due to the fact that I have always taken as a standard for comparison, as a gauge of the correctness of any theory,

not the personality of the one who advanced the theory, but the result of such theory upon the patient. If the patient fails to get well, then the theory should be rejected, no matter how exalted the position is of the one who advanced such theory. The sooner this view is accepted by the medical profession universally the sooner will medicine get on safe scientific ground. Our watchword must ever be the health of the one who consults us, and it is our duty to accomplish this by any means irrespective of, whether by so doing, we conform to the

teachings extant or repudiate them.

In the issue of May 24, 1902, of the *Philadelphia Medical Journal*, I described for the first time insufficientia pylori as a sequela of chronic gastritis. Since then I have repeatedly written on the same subject. At that time my writing was the result of purely logical deduction; it was simply a matter of inference; I had had no anatomical evidence to guide me. But now, some five years after my first description, the actual existence of the condition has been proved by an eminent London surgeon, who had made it his business to examine the condition of the pylorus at each laparotomy. The condition which I have described as insufficientia pylori presents the identical clinical picture of that described as achylia gastrica. But achylia gastrica is presumed to be a functional disease, a sort of nervous disease, and I have never relished "nervousness" as a cause of any disease. Of course, a disease, nervous in origin, must needs behave and react nervously to treatment-i. e., some time the patient feels better, but mostly not. No wonder the physician had rather see such patients go to some one else, and so it is that with the diagnosis of achylia gastrica one best prescribes the impossible. For the poor patient one advises a high priced watering place several thousand miles away from home, and for the rich nothing less will do than an automobile trip to Mars, but without any Wall Street ticker attached to it by wireless. Thus becomes justified the advice that with the diagnosis of achylia gastrica leave all hopes for a cure behind.

Somehow or another I became quite restive about that disease, especially as I began to see a surfeit of achylics, and at one unfortunate moment I decided to delve into the mysteries of the achylic stomach. Hold on, I thought to myself. Next time an achylic comes I shall have him come again the very following day and shall wait but half an hour after he has eaten his test meal. What a shock to my achylic conceptions right after the first intrusion! Why, I found absolutely good digestion. I found that the chyme showed all the qualifications of a good stomach. That unexpected experience only whetted my appetite for more experiments, which I continued, still obtaining the same results, namely, I had found good digestion at a period earlier than one hour after the eating of the breakfast. What wonder that my untutored belief in achylia gastrica began to vacillate, and slowly but surely the achylic yoke became more and more burdensome to me, unbearable. By degrees and with greater experience, my faith in achylia gas-

trica melted away.

In the clinical picture described as achylia we are asked to assume that the absence of chyme one hour

after the test meal denotes the condition of absence of all gastric functions save motor, but such is not the case. For, if, instead of waiting after the eating of the test meal a full hour, I waited only half or a quarter of an hour, I almost invariably found good digestion. Hence the very stomach which had to be condemned, if the diagnosis of achylia gastrica was to remain, showed remarkable vivacity if its sanctuary was invaded earlier at an unexpected mo-Apparently the trouble was not so much with the stomach as with the diagnosis. After mature deliberation I found the diagnosis of achylia untenable, and concluded to call cases which presented the achylic aspect chronic gastritis with supermotility. This combination I thought worth while handling, and I felt very proud of this product of literary meditation. I called it chronic gastritis, because the patients gave the histories of long suffering, and the reason why I termed it supermotility was that the stomach seemed to show an express speed in expediting its contents. For a while I felt quite exultant over my prowess. Now it was chronic gastritis with hypertony, and I was very happy. However, my patients persisted in not getting better, and certainly in not being cured. Of course, it was never my fault; I treated as I was taught. That I had changed the name, what difference? It meant the same condition, and so I continued to treat my patients as if my diagnosis had been achylia. Somehow I soon tired of that beautifully sounding combination, and finally, by the process of evolution and elimination, as described in my first article, I reached the conclusion that not the entire stomach was to blame in those cases, but only the very tail of it, the pylorus.

It would seem that Einhorn in his zeal was car-

ried away by the enthusiasm of the novice. Otherwise he should have asked of himself the same question as I, and he might possibly have come to the same conclusions. The more I looked into the matter the more I became convinced that I was dealing with no other condition than the weakening of the pyloric sphincter, which followed a previous overtaxing of it. This previous overtaxing and overirritating may have happened within the memory of the patient, or it may have had its origin in the very first days of his life and hence been unknown to him. This weakening, this relaxation of the pyloric sphincter I termed insufficientia pylori. Let us think over the practical value of these terms. Diagnosticated as achylia gastrica, the outlook is dubious at best, and rather bad as to the ultimate cure. The same clinical entity diagnosticated as insufficientia pylori, and the cure is not only a positive certainty, but betterment begins to manifest itself within a few days. Might not Einhorn test his cases of achylia a second, third, or even a fourth time, and then either refute my statements or accept them? The most absolute and exact knowledge concerning the actual condition of the stomach is of the utmost importance, not from a fancied academical standpoint, but for the purpose of curing

the sufferers.

In my first article I explained the method of reasoning by which I arrived at the conclusion of the existence of insufficientia pylori, and I then based my views on the existence of the following facts:

I. The pyloric region is the lowest part of the stomach, hence all ingesta drop there by mere gravitation. 2. The pyloric region is the most often affected by disease. This is a fact which stands proved by autopsies both in vivo and post mortem, and is easily explained by the preceding fact, namely: since all matters drop down to the lowest, to the pylorus, hence also the noxious matters, which must needs affect the part with which they come in direct contact. 3. The pyloric sphincter is spastically contracted by irritation. Such contraction depends on the degree, severity, and length of time of such irritation. For a certain length of time the pylorus will be able to respond to excessive irritation with strong contraction, but sooner or later the muscular sphincter, whipped into excessive exercise, must and does relax. This constitutes the condition of insufficientia pylori. The muscle of the pylorus behaves identically in the same way as does the muscle in any other part of the body. We may chop wood for a number of hours in succession, but we cannot do it incessantly; the muscles, we say, tire out. The tiring out is gradual in its development, hence there are several stages of the relaxed pylorus.

My present writing has no other motive than to impress upon the profession the absolute necessity of recognizing insufficientia pylori as a disease of the stomach which is of very frequent occurrence; it is the natural sequel of chronic pyloritis, which latter condition, presumably always, is preceded by a stenotic condition of the pylorus. The stenosis gives way subsequently to insufficiency. stenosis need not be demonstrable anatomically, but it is the stenosis produced by overcontraction, it is the stenosis which I have termed "stenosis pylori ab irritatione." It is this condition which so often causes such grave and fatal mistakes. I have seen it mistaken for diabetes, valvular lesion of the heart, grave kidney disease, asthma, tuberculosis, and a hidden carcinoma. All these supposed diseases rapidly vanished after recognizing the true condition of insufficientia and treating the patient for this.

I cannot forget the one case in which a physician who called me in consultation to a man supposedly dying from cancer was entirely nonplussed by my declaration that the patient would be well in a few weeks; my prognosis proved true. Although this physician and his predecessors concurred in the diagnosis of cancer, the patient suffered from nothing worse than insufficiency of the pylorus. Miraculous indeed it appears when a patient nearly seventy, who had suffered ever since he was nineteen, who was well acquainted with the several countries of two continents, where he looked for relief, who had consulted physicians by the score during this long period, who had to abstain from many articles of food in order to lessen his suffering, who suffered mostly after eating meat, and who can now enjoy life with but insignificantly little restriction in his diet. This was accomplished after but a few weeks of treatment.

This case is an illustration of one out of many dozens, if not hundreds, of cases which presented the typical picture of "achylia gastrica." Here is a case of another, a man of fifty-eight. He came to me with the diagnosis of valvular lesion of the

heart on January 17, 1008. The usual test meal was given him, and his stomach was aspirated. No sign of anything. He came again the following day, and this time I attempted to aspirate half an hour after he had taken the test meal. Again the stomach was found empty. He came the following day; this time only fifteen minutes elapsed between the eating and my attempt to aspirate, but again unsuccessfully. I made him come again the following day, and this time the patient was put on his left side for fifteen minutes immediately after his eating. This time I did aspirate about two c.c., which, however, gave a negative reaction to tropaeolin, but a positive one to Toepfer's test. Here we see a case which certainly represents "achylia"—and the very latest phrase Einhorn uses in describing the meaning achylia is found in his article Intestinal Dyspepsia (Berliner klinische Wochenschrift, No. 23, 1908), in which he says: "By the term 'achylia' is denoted the 'absolute absence of any secretion.'" But this case did show some sort of secretion after the patient was put on his left side for fifteen minutes. is only one instance of many more. The subsequent history of this case goes this way. March 18th, the aspiration of the test meal fifteen minutes after eating gave 38 c.c., tropaeolin negative, but Toepfer positive. The aspiration of test meal half an hour after eating on the 11th of April gave 2 c.c., but tropaeolin was positive, and on the 13th of June the aspiration one half hour after eating gave 6 c.c., with the tropaeolin very positive. This patient's supposed heart disease was gone pretty soon after treatment for insufficiency of the pylorus was instituted, and he considers himself now a well man. Does the usual treatment advocated in achylia achieve such results?

Now to come back to the subject. Insufficientia pylori is that condition in which one hour after eating the test breakfast either no contents at all are aspirated from the stomach or but a few cubic centimetres. If one or two cubic centimetres are aspirated and tropaeolin gives a positive reaction, then we need go no further; we have the diagnosis of insufficiency. But if this one or two cubic centimetres of contents is imbedded in mucus, without even an acid reaction, or if no contents at all are aspirated, it becomes our duty to search further, and this with double purpose. First we must ascertain the degree of the relaxation of the pylorus, and secondly we must make sure if there is any glandular activity left in the stomach. This is accomplished by giving the patient repeated test meals, one morning after the other, and shortening every day by fifteen minutes the time of waiting between the eating of the test meal and the time of aspiration of the stomach. If we can aspirate no contents, even fifteen minutes after the eating of the test meal, then the patient is told to come again the following day, when he is put on his left side for fifteen minutes, and then the stomach is aspirated. But also this may prove unsuccessful, and then the patient comes again the following day, and now I give him a "coffee test meal," which consists of 35 grammes of roll and 200 c.c. of black coffee. The patient is treated as on the day before-i, e., by fifteen minutes' waiting; this will usually suffice for

the diagnosis. If there is no complete insufficiency i. e., if the pylorus is still capable of answering to stimulation, the coffee will do it, the pylorus will then contract.

Just let me see what is the explanation given for the absence of chyme in achylia. The fact that no contents are aspirated has been explained very philosophically, that because of the absence of stomach digestion, because of the achylia, the muscularis ventriculi, like a good fellow, obliges and shoves and pushes the chyme, if chyme it should be called at all. into better and more convenient quarters, into the intestines, here to see its finish. That is in plain medical vernacular, because the stomach cannot work, therefore it overworks itself to get the ingested food into the intestine in rapid transit style, and "there you Just because of the fancied existence of atrophy of the mucosa, which, by the way, autopsies but rarely attest, there is a manifestation of true fraternalism in the muscularis, and it is this good fellow which, to oblige, pushes things along.

The absence of food in the stomach is attributed to hyperkinesis, overmotility, hypertony. Now, overmotility of the muscularis may manifest itself either in an increased number of contractions or in deeper contractions or in both. These contractions travel from the cardia towards the pylorus with like intensity issuing from the same irritating cause. Overmotility means overaction, hence also deeper contractions, and a deeper contraction of the pyloric region can effect only its more spastic occlusion. Here again I wish to call attention to the fact that the opening and closing of the sphincter of the pylorus is effected through the ordinary peristalsis of the stomach and not through any special nerve function, namely, the force of the peristaltic wave of the stomach, which causes a comparatively small diminution of the diameter of the stomach, is ample enough to entirely occlude the lumen of the pylorus. This it does not because of anything else than that the lumen of the pylorus is very small, so that if the force of the peristalsis is sufficient to produce a diminution of a quarter of an inch at each end in the diameter of the stomach, the same force in producing a like diminution of one quarter of an inch in the pylorus closes the calibre of the pylorus. The closure of the pylorus is produced by the active peristaltic contraction of the muscularis; the opening of the pylorus is a passive act, is a relaxation, a recoiling of the muscularis. There is no need to call in the operation of any special nervous action or nerve centre to account for the opening and closing of the pylorus. Naturally, the pylorus will respond to peristaltic action only when it is in a normal condition. The moment we speak of increased gastric motility, of hypertony, we must at once admit that such hypertony also operates on the pylorus, and the result of this must, of necessity, be the spastic closure thereof; and spastic closure of the pylorus must give and does give a larger quantity of chyme after the test meal has been eaten, simply because the gastric contents are forcibly held back in the stomach by the spastic contraction of the pylorus. Therefore we can see how highly illogical and preposterous is the conclusion that the entirely too premature escape of the ingesta from the stomach is due to

any overaction of the muscular coat of the stomach. Absence of chyme in the stomach one hour after the test meal was eaten precludes the possibility of overmotility; overmotility guarantees spastic contraction of the pylorus, and spastic contraction of the pylorus gives a large quantity of chyme, instead of absence of chyme, which is taught as diagnostic of achylia.

As I stated in my first article, in 1902, I deduced the existence of insufficiency of the pylorus from the analogy of the relaxation of other muscles of the body following an overexertion of such muscle or group of muscles. If we accept the exist-ence of an overexcited stage of the pyloric sphincter at any time and for any continuous length of time, the relaxation of such overstimulated muscle must at some future time follow as a logical consequence. If we accept the existence of pyloric spasm, and this is no more denied, we must admit that such repeated spastic contractions will gradually weaken the pyloric muscle; then relaxation must ensue. If the pylorus has finally and entirely relaxed, the ingested food instantly escapes from the stomach by mere gravity. To counteract gravity is why I place the patient on his left side for fifteen minutes after the eating of the test meal. The finding of chyme then, fifteen minutes after eating, which I did not find when I had the patient in the usual sitting position, sufficiently testifies to the correctness of the view that the escape of the ingested matter through the pylorus is due solely to the changed position of the body, to gravity. If there is nothing else, this test alone is sufficient to prove the existence of the insufficiency of the relaxed condition of the pylorus. For we could not very well assume that the allegiance of the ventricular muscle to the intestine was binding only in certain positions of the body, and that the stomach muscle had stipulated as the one and necessary covenant in its contract with the bowel to work over time only when the person was standing or sitting, but that any other position would mean an infraction, and therefore a violation, of the agreement whereby the stomach felt itself relieved from any obligation to "overmotili-' Overmotility of the muscularis out of sympathy for an atrophy of the mucosa-what atrocious nonsense! What incongruities are, only too often, doled out to us under the cloak of scientific Were it but a question of academical finesse we might condone such grandiose infantile philosophy. But it is not. The diagnosis of achylia gastrica condemns the patient to an indeterminate sentence of suffering, while the diagnosis of insufficientia pylori prognosticates absolute and speedy recovery.

My earlier monographs on insufficiency of the pylorus relate to a condition which necessarily follows a chronic affection of the pylorus. True, my first article is headed Insufficientia Pylori, a Sequela of Chronic Gastritis. But since then I have had to modify my views as to the gastritis. Gastritis suggests the involvement of the entire stomach, which is comparatively seldom the case. Instead, it is only the pyloric region which is mostly the seat of damage. However, my first article sufficiently dwells on the pyloric region, and one who reads this article cannot fail to see that I meant the pyloritis instead of gastritis. Thus corrected I would now

say "insufficientia pylori, a sequela of chronic pyloritis." The insufficiency is the natural sequence of the chronic pyloritis, which is clinically evident by the pain in the pit of the stomach. Certainly this view of insufficiency is in marked contrast with the assumption of insufficiency being of "nervous I do not assert that I discovered the conorigin.' dition of insufficiency of the pylorus as a thing existing. I only allege that I first described insufficiency as being the natural sequel of chronic pyloritis, and that its occurrence is very, very frequent, that it is not of any nervous origin, but that it has a physical existence. Hemmeter has quite a good article on insufficiency in his textbook, but, unfortunately, he classes it among the occasional neuroses of the stomach.

For five years my views on insufficiency of the pylorus had no other basis than my reasoning. But now its anatomical existence is subscribed to and verified by Moullin, an eminent London surgeon. Says Moullin (Pyloric Stenosis and Conditions of the Pylorus During Life, Lancet, January 19, 1907): ". . . I found that the size of the pylorus varied from that of a channel which could easily admit three fingers . . . to that of a tiny orifice. . . . The former was in a patient (of whom) the pylorus was so indefinite that it was difficult to find. The sphincter could scarcely be felt, and the stomach and intestine seemed to form one continuous canal without a break." From the title of this monograph is indicated at once the object of the writer, viz., pyloric stenosis. Moullin was not interested in insufficiency, but he says: "Between these two (the channel wide pylorus and the pylorus in which the orifice could scarcely be felt) I have met with every grade." In other words, based on actual experience from laparotomies and autopsies and therefore based on indisputable evidence of facts, not theories. Moullin asserts exactly what I have repeatedly stated, that there is a channel wide pylorus, hence there is the actual presence of the insufficiency which I have been teaching since 1902, and that there are several stages of insufficientia pylori, at which conclusion I arrived not from autopsies, but from reasoning and deductions from clinical facts.

In conclusion I wish to address a few words to the general practitioner. You, general practitioner, are called upon not only to make a diagnosis, not only to treat, but, especially, to cure. If you do not cure, some Eddyite or other sort of quack will take your living away. Before you accept the diagnosis "achylia gastrica" or "destruction of the lining of the stomach," make sure that it is so. Insist upon repeated test meal examinations as outlined in this monograph, and, when you have found the case to be one of insufficiency of the pylorus, then treat accordingly. In my previous articles the symptoms and treatment are given.

Our Menders' Discussions.

A SERIES OF PRIZE ESSAYS.

Questions for discussion in this department are announced at frequent intervals. So far as they have been

decided upon, the further questions are as follows LXXIX.—How do you treat sick headache?

October 15, 1908.)

LXXX.—How do you treat asphyxia neonatorum? (Answers due not later than November 16, 1908.)

LXXXI.-How do you treat chronic eczema? (Answers

due not later than December 15, 1908.)

Whoever answers one of these questions in the manner most satisfactory to the editors and their advisers will receive a prize of \$25. No importance whatever will be at-tached to literary style, but the award will be based solely on the value of the substance of the answer. It is requested (but not required) that the answers be short; if practicable, no one answer to contain more than six hundred words.

All persons will be entitled to compete for the prize, whether subscribers or not. This prize will not be awarded to any one person more than once within one year. Every answer must be accompanied by the writer's full name and address, both of which we must be at liberty to publish. All papers contributed become the property of the JOURNAL. OUR READERS ARE ASKED TO SUGGEST TOPICS FOR DISCUSSION.

The prize of \$25 for the best essay submitted in answer to question LXXVIII has been awarded to Dr. Charles Floyd Burrows, of Syracuse, N. Y., whose article appears

below

PRIZE QUESTION LXXVIII.

THE TREATMENT OF ACUTE CORYZA.

BY CHARLES FLOYD BURROWS, M. D., Syracuse, N. Y.

Acute coryza, even more than dyspepsia, is one of the commonest disorders which general practitioners are called upon to treat. "Cold in the head," or "catarrh," as it is popularly termed by the laity, is an acute infection of the nasal mucous membrane brought on usually by exposure to cold, and is a self limited disease, though its course may be cut down to a minimum and its discomforts ameliorated by early and rational treatment.

It begins with stuffiness in the nasal passages, suffusion of the eyes, sneezing, headache, chilliness, and malaise. It often ushers in other acute and more serious febrile diseases as measles, the grippe, etc. But in answering the question, How do you

treat acute corvza, I take it that this query is meant to apply to the ordinary catarrhal cold, which every one so often experiences in the changeable weather

of winter, spring, and autumn.

If coryza is seen in its initial stage the treatment consists, first, in promptly administering a dose of calomel-one grain in divided doses, followed a few hours later by a saline cathartic. Five grains of Dover's powder should also be given at once along with quinine, grain v. The quinine may be repeated every two or three hours in diminishing doses. If fever is present and the skin hot and dry tincture of aconite in drop doses every hour or two will relieve this and also will tend to dry the nasal mucous membrane. The old fashioned treatment of prescribing a hot mustard foot and leg bath for ten or fifteen minutes and the ingestion of a glass of hot ler counte : Russian tea while coffed at and discountenanced by many physicians, I believe to be worthy and very useful. These measures tend to open the pores of the skin, produce sweating, and relieve congestion of the head by drawing the blood to other tissues, and so equalizing to some extent the circulation.

After this treatment has been instituted a patient should be confined to a bed or a couch, with a hot water bottle to the feet, warmly covered, and the room thoroughly opened to admit all the fresh outdoor air available. Weston, the pedestrian, in his famous walk from Portland, Me., to Chicago, Ill., found that when he began to suffer from a cold that by continuing persistently along his way he could soon walk it off under the brisk outdoor exercise which he was subjecting himself to. While such treatment would prove too rigorous and heroic for practicability among most of our patients it teaches a common sense lesson in treating colds. The old idea of cooping oneself in a red hot, stuffy room, and avoiding drafts and fresh air-especially "night air"-as sure pneumonia producers, has passed away along with many other old fogyisms. Nowadays the benefits of breathing fresh cold outdoor air are realized forcibly in all respiratory affections, whether of the lungs, throat, or nose.

Locally greasing the nose externally with lanolin is certainly a measure which relieves the difficulty in breathing. Another old fashioned idea, but not to be despised! Every hour the nasal passages may be irrigated with a warm boric acid solution. This carries away mucous discharge, allays irritation and congestion—so affording relief. Care must be insisted on that violent blowing of the nose is not resorted to after its use, as middle ear trouble may occur from forcing fluid and germs through the Eustachian tube. Inhalations of menthol following this douching are relieving and soothing, as is also the application to the nostrils of pledgets of medicated cotton wool, which is now on the market, for such conditions. Spraying the nasal mucosa with or applying applications of such drugs as cocaine and suprarenal extracts, while affording much relief at once by constricting the mucosa and bloodvessels, serve no other therapeutic or curative effect, and tend to prolong and make a case worse when the after effects of these drugs follow. Therefore they should never be used in treating acute corvza.

In cases of coryza which have progressed for a day or two beyond the initial stage when one is consulted the treatment varies somewhat. A dose of calomel should be prescribed, as outlined before, small doses of quinine administered, frequent irrigations with the boric acid solution recommended, and outdoor air in quantity ad libitum ordered. These measures will relieve the annoying symptoms and hurry the termination.

Fresh air in abundance then, with rest, opening of the bowels, frequent irrigation of the nasal passages, a hot pediluvium, warm drinks, and a few judicious antifebrile drugs will accomplish all one can hope for in cutting short an attack of acute coryza and allaying its discomforts.

Such a treatment, even with its foothbath and anomiting of the nose, has the advantage also of

producing a helpful psychic effect on a patient-an effect which even in cold in the head is not to be overlooked, thanks to some lessons learned from Christian science and suggestive healing-and will prove therefore more satisfactory to him and more advantageous to a physician than the usual hurried routine of handing out a few rhinitis tablets, whose effect is usually to disorder the stomach. I believe it is the only rational common sense therapy for this disagreeable every day affliction—acute coryza.

1001 EAST GENESEE STREET.

Dr. Beverley Robinson, of New York, says:

If acute coryza is seen at its earliest stage, when the patient has begun to sneeze, with, or without, slight catarrhal discharge from the nasal passages, we should try to abort it. A few doses of quinine will occasionally accomplish this. When used it should be in two to four grain doses, repeated not oftener than once every six hours. Given in larger doses, or more frequently, it acts no better and sometimes acts as a depressant, and certainly not as a tonic. Quinine hydrochloride is the preferable salt. It is more acceptable to the stomach than the sulphate and is not so apt to occasion tinnitus or unpleasant aural symptoms.

Personally, after numerous trials, I have concluded that of divers prescriptions to abort a case of acute coryza none will accomplish it so frequently and with apparently so little objection as ammonium carbonate. This drug should be given preferably in mixtura amygdalæ, or in water with a little syrup of acacia and orange flower water, as a flavoring agent. A grain to the dessertspoonful is a suitable dose, repeated every hour for twelve consecutive hours, and later at longer intervals. Every two or three hours is frequent enough for the sec-

ond twelve or twenty-four hours.

If at the expiration of forty-eight hours the attack of acute coryza is not entirely aborted it is useless to continue the remedy. If ammonium carbonate is continued too frequently and too long it becomes a notable depressant of the circulation and sometimes occasions unpleasant symptoms of cardiac disability of temporary nature. Occasionally I substitute the aromatic spirit of ammonia for the carbonate in twenty drop doses every two hours. diluted with water, but it is not so efficacious as the former. Ammonia carbonate and also the aromatic spirit eliminate themselves from the body through the nasal mucous membrane and are thus useful locally. It is probable that they modify favorably the inflamed pituitary. It is also probable that not infrequently they prove fatal to the microbes, which are clearly present at times, and which doubtless are connected as a causative factor with the inception of acute coryza. I have come to regard ammonium carbonate as nearly a specific in the treatment of acute corvza, when it is used soon enough, repeatedly, and in suitable doses. While it succeeds more frequently than any other drug, or combination of drugs with which I am familiar, and with less unpleasant after effects, it fails frequently to accomplish the purpose of aborting the coryza. In my judgment, this is true when the corvza has not been treated with it at the initial stage, and in accordance with the precise manner I have indicated.

Among the other remedies indicated to cure, or . rather abort an attack of acute coryza, I would moderately recommend the use of the Turkish bath. To a patient in previous good health and not much past middle life, it may usually be recommended as a safe and oftentimes efficient treatment. The bath should be taken, however, at a suitable time after eating, when the patient is not unduly fatigued, when he has time to give to it, and when, too, the attention of the attendant at the bath, who gives the after massage, or rub down treatment, is thoroughly available and not pressed for time by numerous other calls from bathers. When all the foregoing conditions are not strictly attended to, the Turkish bath may be harmful instead of useful and aggravate the coryza rather than abort it.

Locally, there is no spray, powder, inhalation, which per se will abort a coryza successfully. I have tried a large number of them, of different kinds, and at different times have believed I had found a panacea. Invariably I have been disappointed, and at present I have given up the search-

When after the effort has been made to abort an attack of acute coryza and failed, it behooves us to institute other treatment. The most effective and least injurious of these is the combination of sweet spirit of nitre with spirit of Mindererus. Nitre in doses of twenty minims and spirit of mindererus, a dessertspoonful repeated every two or three hours, plain or diluted with a little water, will be found not unpleasant and effective. It is a slightly stimulating mixture, and with it the arteries are relaxed and the skin rendered more active. While taking it one must be careful not to sit in a draught or go into the open air unless the weather is very mild. If this indication is not attended to the coryza is aggravated, and laryngitis and bronchitis may develop. Indeed, it is rare, after two or three days at the most, that an attack of acute coryza, if it still persists, is limited strictly to the nasal passages. Tickling in the throat and slight, recurring cough ensue, with some repeated expectoration of frothy mucus, which all indicate the implication of the respiratory tract further along. At times, under these circumstances, the coryza is seemingly better, and there is less blowing of the nose, less discharge from the nasal passages, and a freer current of air through them. Again, these symptoms are no better; indeed, they are somewhat aggravated, and, in addition, the other symptoms just re-

Locally, when the acute coryza has lasted several days. I have believed that bismuth subnitrate with a little powdered acacia and morphine blown into the nose with a simple powder blower was of service in lessening discharge and irritation. Preferably, however, to this, in many instances, is the repeated inhalation of the vapors from equal parts of oil of eucalyptus, camphor, and menthol. many years I have made use of this combination in becomes vellow and notably thick and abundant, or it may be decidedly purulent, I have repeatedly found that no application is so useful as the following, used night and morning, or even three times in

| P_{i} | Oleoresin of cubeb, m xx |
|---------|-----------------------------------|
| | Powd. camphor,gr. xi Glycerin, |
| М | White petrolatum, |

This ointment should be applied to either nostril with the tip of the finger, and then while moderate pressure is made to occlude the other nostril, the ointment is sniffed up, or drawn upwards and backwards in the nasal passage until it is felt or detected in the nasopharynx. What amount enters the pharynx is simply expectorated. After drawing up the ointment into one nasal passage until it is thoroughly coated, the same process should be used for the other side. By the use of this ointment the sensitive and inflamed pituitary membrane is protected against the air, atmospheric changes, dust, etc., and no doubt, also, a decidedly curative effect is produced by these combined agents, which are the most effective I have thus far found.

The foregoing treatment of acute coryza is practical, efficient, and has stood the test in very many instances and through a long term of years.

Finally, I would add that it is decidedly wise to always take a purgative dose of Rochelle salt in the morning, at the initial stage of acute coryza. Frequently coryza means, when properly translated, a susceptible mucous membrane, due mainly to congestion caused by lithæmia, and brought on by overeating or too much alcoholic stimulation.

Dr. W. Peyre Porcher, of Charleston, S. C., writes:

It has been hymorously said that "A man must

It has been humorously said that "A man must be mighty unlucky who could not even catch a bad cold," but there has been no equally axiomatic statement in regard to getting rid of one. This might be expressed as follows: Free purgation, free diaphoresis, stasis. Thomas Watson, the English physician, is reported to have said that the cure for a cold was a teaspoonful of laudanum. By this he meant that no other drug could control the circulation and hence limit the inflammation and secretion in the nose like opium. The most certain method of aborting a coryza is as follows: First night, free catharsis (preferably mercurial). Second night, drink eight or ten ounces of very hot water to which some sugar and spice and one half ounce of whiskey have been added. Exercise by rapid walking or otherwise until profuse diaphoresis has been produced. Take Dover's powder, grains 10; or camphorated Dover's powder. Retire immediately under warm bed clothing. The result will be certain. There will be an abatement of all the symptoms. The raw, sore feeling in the throat and nose, the profuse discharge from the nose and the throat will all have ceased. Here we have first the revulsive effect of the purgative, next the profuse diplace is produced by the hot drink, together with the stimulant, and the exerise, and finally the conunling action on the circulation of the opium in the Dover's powder.

By far the adjuncts most valuable to this in the treatment of a cold are warm sunshine and healthy critic. By this I mean exercise sufficient to produce free diaphoresis and a general emptying of the enunctories of the system. Of course there are other methods and other medicaments by which the cresults can be accomplished, such as bella

donna, pilocarpine, Turkish baths, etc., etc., but the mentioned procedure is far more certain and effective than any other.

If the coryza is accompanied with fever antipyretics must be administered, always proceeded by a mild cathartic to cleanse the alimentary tract.

Locally a weak mentholated oil to which a little cocaine has been added may be sprayed into the nose occasionally, and will afford considerable relief from the sense of congestion and swelling in the nose, but local applications do not abort the disease, and constitutional treatment is always imperative. The so called anticold combinations are usually ineffective on account of the lack of other measures and improper administration. Therefore all the specifics which have been extolled for the cure of coryza have failed in most instances.

(To be continued.)

Correspondence.

LETTER FROM LONDON.

Opening of the Medical Schools.—Tuberculous Disease in the United Kingdom.—The New King's College Hospital.—Indecent Advertisements.—The Late Sir Arthur Vernon Macan.

LONDON, October 6, 1908.

Last week the new medical session commenced with the opening of all the medical schools. For the last few years the custom that was formerly very common, that of having opening addresses on these occasions, has fallen somewhat into abeyance, and with few exceptions the opening was marked merely by an introductory speech from the dean, followed by the distribution of prizes, and an "Old Students' in dinner in the evening. Opening addresses were given at King's College by Dr. Macalister, of Cambridge, at Charing Cross Hospital by Sir Patrick Manson, and at the Middlesex Hospital by Mr. Rudyard Kipling. The last was a very humorous discourse in Mr. Kipling's best vein. The schools and medical societies will soon be in full swing again.

The war against tuberculosis in England is being waged in various ways with great assiduity. The death rate from the various forms of tuberculosis has steadily declined in England, Wales, and Scotland, until it is now about half of what it was fifty years ago. On the other hand, in Ireland there has been a steady increase in the death rate from consumption. An attempt has been made to explain this unfortunate increase of the death rate from tuberculous disease in Ireland on the ground that there is a constant emigration of the young and healthy adult population of that country, which, leaving behind an undue proportion of aged and weakly individuals, necessarily raises the death rate from all diseases, including that from tuberculosis. It has been shown that emigration has been responsible for the statistics which have shown an apparent alarming increase of insanity in Ireland during recent years, and on analogous reasoning it may also be assumed to influence seriously the mortality statistics for the country. This argument is strongly supported by the fact that the greater part of the

increased death rate from tuberculosis in Ireland is accounted for by deaths occurring between the ages of fifteen and thirty-five years, which is just the period which is most affected by emigration. This alarming increase of tuberculosis in Ireland led to the introduction of the bill for the compulsory notification of phthisis (Ireland), which will probably

pass into law this session.

A similar bill will probably be passed in England, as Dr. A. Newsholme, principal medical officer of the Local Government Board, speaking at the Washington International Congress on Tuberculosis, on the authority of Mr. Burns, made the announcement that the board proposed to put upon the poor law medical officers the duty of notifying to all sanitary authorities who requested the information all cases of pulmonary tuberculosis occurring among patients who were a charge to the parish. Such an order, to be of any use, will also make it compulsory upon the guardians and their staff to notify changes of address of parochial patients suffering from pulmonary consumption, and no doubt the details of such notification will be arranged. In the curative treatment of this disease the campaign is also being carried on. Sanatoria are largely increasing in numbers, with good results. These institutions are, however, so costly to maintain that most of them have to make some charges to the patients, and the poor are thus deprived of their benefits. An interesting experiment was made in this direction by Dr. Lyster, of Chelmsford, who began operations about eight years ago. He organized a system of pervious canvas shelters, which was done at comparatively small cost, and in these the patients lived. The result has been that for two years past he has not had a single fresh case of tuberculosis in his district, and all the cases he now has under treatment were "imported" from other districts. actual cost of erecting and furnishing a shelter for one person was £25 and for two persons at the rate of £15 each, which is decidedly less than the cost at a sanatorium.

It is now five years since it was first decided to remove King's College Hospital to South London, and although for some time but little progress was made with this scheme, the work of constructing the new buildings has advanced rapidly during the past six months. The outpatient and casualty departments are well on the way toward completion, and the erection of the administration block, together with some of the wards, will be proceeded with very shortly. The new hospital will have 600 beds when completed, and if present plans are carried out, will probably be one of the finest hospitals in Europe. For some time King's College Hospital has occupied a position in which, owing to the clearance of slums and the dispersal of the poor population of the West Central District, there has been no real need of a large general hospital, while, on the other hand, the new hospital will afford relief to the vast population which surrounds Camberwell Green and is at present without hospital accommodation. The separation of the hospital from King's College will make it necessary for a division of studies to be carried out in connection with medical education at this institution. Such a system was proposed some little time ago for all the hospitals by the University of London, but the proposal did not meet with general approbation. In the present case, however, it is practicable and to some extent essential, as the preliminary scientific work of the medical curriculum (including anatomy and physiology) can readily be carried out at such an institution as King's College, while the actual practice of medicine and surgery will be carried out in the wards of the new hospital and in the laboratories for bacteriology and pathology which will be built in connection with it.

The committee of the House of Commons appointed to inquire into the subject of indecent advertisements and indecent literature generally has just published its report. The committee draw attention to certain anomalies in the law which require amendment. Thus, while it is an offense against the law to affix an indecent advertisement or print to a wall or boarding, it is no offense to place obscene or indecent papers or prints in the letter box of any house. Moreover, it is questionable whether there is power under the existing law to deal with indecent exhibitions in stereoscopic machines. The committee recommend such changes in the law as would remedy these anomalies. They also recommend such statutory definitions of indecent or obscene matter as would render the application of the law wider than at present. Also they suggest that the advertisement or sale of drugs or articles designed for procuring abortion should be made illegal, and that the advertisements of articles designed for the prevention of conception should be rendered illegal. It will be the wish of the medical profession in England that the various reforms suggested by the committee may speedily be brought into effect.

The death has occurred of Sir Arthur Vernon Macan, B. A., M. B., M. Ch., King's professor of midwifery, Trinity College, Dublin, and obstetric physician to Sir Patrick Dun's Hospital, Dublin. He was graduated in 1868 in the University of Dublin, and subsequently proceeded to Berlin and Vienna, where he spent several years in study, particularly in that of midwifery and gynæcology. He was appointed to the mastership of the Rotunda Hospital in 1882, and while there he instituted several reforms, especially an improvement in the nursing system, and there he performed the first Cæsarean section that was done in Ireland. He had been a president of the British Medical Association and also served as president of the British Gynæcological Society. He had written numerous works on obstetrical and gynæcological subjects.

Therapeutical Notes.

For Tenia in Infants.—The following is prescribed by G. Bardet:

| Oleoresin o | | | | |

NEW YORK, SATURDAY, OCTOBER 31, 1908.

PROFESSOR CALMETTE'S HARVEY LECTURE.

The first of this year's lectures given under the auspices of the Harvey Society was delivered by Professor A. Calmette, of Lille, last week, and the subject was one with which his name has been intimately associated for years, namely, Intestinal Infection and Immunity in Tuberculosis. As those who have followed the literature are aware, Calmette argues strongly for the lymph path of infection, and sees in the digestive tract the chief portal of entry for the virus. According to him, aerial infection, either by means of spray particles (Flügge) or through dust containing tubercle bacilli (Cornet) is very infrequent. In fact, he alludes to the normal asepsis of the respiratory tract as arguing in favor of a strong natural defense against bacterial invasion from that point. It would be interesting to know just what data Calmette has concerning this point. Is the mucous membrane of the trachea and bronchi really aseptic under normal conditions?

Lest his readers associate the idea of intestinal infection with the well known view of Behring, Calmette is careful to emphasize the point that he does not believe the milk of tuberculous cows plays an essential rôle in human tuberculous infection. While admitting that such milk is dangerous, especially for young infants, he believes that this factor is slight when compared with the danger lurking in human by the the coeffet by a confumptive. In considering the various ways in which human tubercle bacilli may reach the food and so the intestinal tract, Calmette speaks of flies as an important factor in this transmission. Although we are thoroughly in sympathy with the movement for the suppression of the fly nuisance, we cannot share his view of their importance in the transmission of tuberculous infection. It is well known, of course, that the fly is an important element in the spread of typhoid fever and other diarrheal diseases. The typhoid bacillus, however, is highly saprophytic, and mutiplies rapidly when inoculated into a suitable medium, such as milk. In the case of the tubercle bacillus this is not the case, and it would therefore be necessary for a fly to deposit a considerable amount of tuberculous material on the food in order to carry infection to

In order to establish the path of absorption from the intestinal tract, Calmette mixed lamp black with the food of a number of animals and observed that the fate of these particles differed in the young and in adult animals. In the former the particles were held back in the mesenteric lymph nodes, while in the latter they often traveled to the lung, producing the typical picture of anthracosis. Similar results were obtained in animals with tubercle bacilli. In the very young the bacilli were held back by the lymph nodes; in the older animals the virus was carried through the lymph nodes into the thoracic duct and so into the right heart. From there the bacilli reached the lungs. Calmette thus gives an anatomical reason, the difference in the density of the filters constituted by the lymph nodes, for the greater proportion of tuberculous mesenteric glands found in infants. The frequency of the involvement of these glands, it will be recalled, was at one time made the basis for computing the relative frequency of intestinal infection. In the future it will be necessary to consider the point raised by Calmette.

Calmette reported some interesting feeding experiments on calves. When these were fed in a single infected meal with a small dose of bovine tubercle bacilli, the animals all became tuberculous, that is, they all reacted to tuberculin in about a month. When the aniamls were tested again, month after month, it was found that after a time some failed to react, and on slaughtering them, these animals were found free from tuberculous lesions. If, instead of slaughtering, one attempted to reinfect such animals, it was found that they were immune to a close of poison certainly capable of infecting other calves of the same age. Instead of feeding with but a single dose of tuberculous virus, he also fed another series of calves repeatedly, at short intervals, with small doses of bacilli. In this case it was found that the animals never ceased to react

to tuberculin, and did not become immune. On the contrary, the infection in these animals developed rapidly and terminated fatally. In order to determine whether the condition in the resistant animals which had been fed but once with tuberculous virus was a true immunity, Calmette felt that absence of reaction to tuberculin was not enough. He examined such animals carefully, to see whether virulent tubercle bacilli were still present in the different lymph nodes in the body. He found that four months after the feeding the bacilli had completely disappeared. This, naturally, is of the highest interest, for the production of immunity in tuberculous disease has remained one of the obscure points.

The immunity thus produced in the animals is not absolute. According to Calmette, healthy cattle can also be prepared by two or three large intravenous injections of tuberculin, and then exhibit considerable resistance. Thus, when injected intravenously with doses sufficient in the controls to produce an acute miliary tuberculosis, these animals always contracted merely a chronic form of tuberculosis, with a very slow development. This is really in line with the view expressed by von Behring four years ago. namely, that pulmonary consumption is a tuberculous infection manifesting itself in an individual already partially immunized. Behring, it may be added, believes that this primary immunizing infection takes place in very early life. It is true that we do not know whether these conditions exist in man, though analogous facts have frequently been reported by clinicians. In view of the efficacy of tuberculin in immunizing the animals, Calmette justly condemns the various methods of immunization in which the living virus is used. His work shows that by the intestinal absorption of a small single dose of tubercle bacilli it is possible to produce an immunity (in animals) of such a degree that for at least a year these animals are insusceptible to large infections through the digestive tract. So far as the duration of this immunity is concerned, it may be of interest to know that, in his "vaccination" against tuberculosis in cattle, Heymanns inoculates the animals each year.

THE SERUM TREATMENT OF CEREBRO-SPINAL FEVER.

In our issue of May 11, 1907, we referred to the attempt to produce an antiserum for therapeutic application in cases of cerebrospinal fever, and in that of January 25, 1908, we referred to the results of the use of this serum in thirty-six cases of cerebrospinal fever in human beings. In the Journal of Experimental Medicine for September 5th, Flexner and Jobling publish a summary of the

results of treatment in four hundred and twentynine cases of cerebrospinal fever in various parts of the world—Ohio, California, Ireland, Scotland, Massachusetts, Pennsylvania, Maryland, and New York. The gross results are that 287, or 66.89 per cent., of the patients recovered, and 142, or 33.11 per cent., died. By eliminating cases that ended fatally in less than twenty-four hours after the injection of the serum, those cases that were of a rapidly fatal, fulminant type, and those that proved fatal on account of secondary or of mixed infections, the mortality percentage is reduced to twenty-five.

It is of course well known that cases of infective disease respond to serum treatment best when the serum is injected within the shortest possible time after the onset of the symptoms, for example, in diphtheria. We think, however, that in publishing results of serum treatment, the percentages of cures and of failures should be calculated upon the total number of cases treated, not upon those treated under the average favorable circumstances. The practising physician must learn, if he has not already learned, to make his diagnosis early and to employ his specific serum treatment at once. The report under discussion contains much interesting material and many instructive tables showing the results of the treatment by age periods, according to the time of the injection, the manner of termination of the attack, the duration of the attacks, the frequency of relapses, and the influence of the serum on the diplococci, on the spinal exudate, on the leucocytosis, and on the frequency of the sequelæ. It is perhaps well to state that all of the cases treated in this series were diagnosticated by bacteriological meth-

The authors conclude that when the antimeningitis serum is used by the subdural route in suitable doses and at proper intervals, it is capable of reducing the period of illness; of preventing, in large measure, the chronic lesions and types of the infection; of bringing about complete restoration of health in all but a very small number of the recovered, thus lessening the serious, deforming, and permanent consequences of meningitis; and of greatly diminishing the fatalities due to the disease.

SOCIETY PROGRAMMES.

We have more than once taken occasion in the past to deprecate the laxity sometimes shown by medical societies in the matter of allowing undesirable papers to be presented at their meetings. We have noted a decided improvement in this respect during the last few years, but a sorry lapse was made by the New York Academy of Medicine recently when it gave an individual the privilege of exploit-

ing a matter connected with the treatment of tabes dorsalis in such a way as to bring him the tremendous advantage of newspaper laudation, an advantage to which at least one shining light of neurology unwittingly contributed by the remarks which he made in the discussion. So palpable was the blunder that the New York Neurological Society very promptly signified its disapproval.

Locomotor ataxia is a disease that offers peculiar opportunities for those whose enthusiasm—not to use a harsher term—leads them to hold out to the public prospects of cure which must prove delusive. But the phenomenal exploit achieved by the man whose paper we have referred to seems to have aroused emulation among those who in various ways hold out an alluring bait to the public; within the last few days there has been shown to us a letter written to a victim of the disease by the proprietor of a sanatorium, in which, after setting forth the therapeutical resources of his establishment, he modestly remarked that not every case of locomotor ataxia was curable!

THE WORK OF THE MANUFACTURING DRUGGIST.

The October number of the Journal of the Michigan State Medical Society contains an article by Dr. Minta Proctor Kemp, of Detroit, entitled What the Manufacturing Druggist Does for the Doctor, in which the author has a good word to say for some of those manufacturing pharmacists whose products are not all official in the United States Pharmacopaia or recognized in the National Formulary. The author first speaks of the biological products, taking the diphtheritic antitoxine as an example. "The cost of production of antitoxine is high," says the article, "on account of the expense of immunizing horses, since all horses are not capable of producing antitoxine, and it may happen that several have to be tried before a susceptible animal is found. When the discovery of antitoxine was made, the manufacturing druggists became interested at once, and the marketed article has been improved at various times since by work done at their expense.'

"When," the author continues, taking up a different class of products, "as the result of research work by physicians and scientists in a manufacturing laboratory, a new remedy is put on the market, it has been considered a convenient protection to inaugurate a trade name for the article, for example, antiphlogistine and listerine. These two preparations are used advisedly, because the preparations have had such a widespread use among physicians that formulas which are nothing more nor less than imitations of them have been placed in the last edition

of the United States Pharmacopæia." The author remarks that the cataplasma kaolini corresponds to antiphlogistine, "and presumably would not have been found in the pharmacopæia except for the intense popularity of the well known preparation of Denver mud, glycerin, etc., which has proved useful and tremendously salable." The author adds that the United States Dispensatory says of the cataplasma kaolini that it was introduced into the pharmacopæia "to supply the demand for an antiseptic poultice," though "it is obvious that the demand was created by the thousands who have used antiphlogistine."

"Antiseptic compound, U. S. P." (by which doubtless the official liquor antisepticus is intended), the author declares to be "a good copy of listerine." Many further examples are cited of the official and semiofficial imitation of proprietary products, "always without credit to the originator." The obvious implication is that this privileged sort of substitution is reprehensible, and we must say that there are many who will admit that the authors of the pharmacopæia and the formulary might have been in better business than that of imitating preparations the prescribing of which under their original names is discountenanced by those who speak for a great part of the medical profession of the country in its corporate capacity.

Then there is the standardization of remedies by testing their physiological action, as in the case of ergot, all of which work appears to be undertaken by the manufacturing houses exclusively. Moreover, many new and useful remedies have been introduced into use as a result of the manufacturers' efforts. In short, a very appealing case is made out for the manufacturing druggists. Of course, there is nothing new in all this, save for the author's implied censure of the pharmacopæia and formulary officials for having resorted to imitation while withholding credit from those who originally devised the preparations imitated; for the medical profession has in the main acknowledged most frankly its indebtedness to the drug manufacturers.

INSTRUCTIONS FOR CONSUMPTIVES.

The Department of Health of the City of New York has issued a handy and very valuable little book entitled Handbook of Help for Persons Suffering from Pulmonary Tuberculosis (Consumption). The city has been deservedly commended for the means which it has taken to succor consumptives, to relieve or cure them of their disease, and to prevent its spread. The little book in question gives full information as to what ought to be done for persons who are thought to be tuberculous, ex-

Aems Items.

cept of course as to the medical treatment, and will serve as a guide to those who wish to take advantage of the varied provisions made for their benefit. It takes the present encouraging view of incipient tuberculous disease, but is far from sanctioning the ostrichlike policy of looking upon the disease as "a cold" or deluding one's self with the idea that pulmonary hæmorrhage comes "from the throat." There is no mystification in its pages; it contains nothing that a grown person of average mental attainment cannot readily comprehend. A copy of it should be kept in every household, for nobody can say that his own family is secure against the insidious attack of the tubercle bacillus, and in case of need, even if the danger seems doubtful, no time should be lost for the lack of such simple instructions as the book gives. We presume that it may be obtained by addressing the Department of Health, Fifty-fifth Street and Sixth Avenue, borough of Manhattan.

Gbituarn.

ALONZO BRAYTON BALL, M. D., of New York.

Last Saturday Dr. Ball died in Boston at the end of a short illness with pneumonia, in the sixty-eighth year of his age. He was the son of a New York physician and a graduate of the College of Physicians and Surgeons, of the class of 1863. After his graduation he served for the full term on the house staff of the New York Hospital, and then engaged in practice in New York. His career was that of a typical and exceedingly able family physician. He became an attending physician to the New York Hospital, to the Presbyterian Hospital, and to St. Luke's Hospital, and a clinical professor in the College of Physicians and Surgeons.

As an oral teacher of medicine Dr. Ball was exceptionally lucid, but he rarely contributed to the literature of the profession, although he was master of a singularly clear and attractive literary style. He possessed the social graces to an unusual degree, and he was critically appreciative of music and the arts of design. As a man he was genial, and his conversation was always interesting and instructive. He was zealous as a citizen, and he was highly esteemed by the profession and by all who knew him.

HENRY DENTON NICOLL, M. D., of New York.

Dr. Nicoll died on Tuesday, October 27th. in New Windsor, N. Y., his native town, at the age

of sixty-four. He was a graduate of the College of Physicians and Surgeons, of New York, of the class of 1866. For many years he had been a well known gynæcologist and one of the surgeons of the Woman's Hospital. He was a man of great amiability, highly respected by his professional brethren.

An Appropriation for the Louisville Medical Schools. The general council of Louisville, Ky., has passed an ordinance appropriating \$25,000, to be used for laboratory equipment for the Medical Department of the University

Women Physicians in France.-It is reported that there are more than six hundred women students in the medical departments of French universities. In Paris alone there are over a hundred women practitioners of medicine, most of them holding official positions.

Buffalo Academy of Medicine.—A meeting of the Section in Surgery will be held on Monday evening, November 2d. The programme will include the following papers: New Aural Surgery, by Dr. George F. Cott; Report of a Case of Primary Ectopic Pregnancy, by Dr. James A. McLeod.

The Manhattan Medical Society.—A stated meeting of this society was held on Friday evening, October 30th. Dr. Dexter D. Ashley demonstrated the Parkhill instrument. and Dr. Ralph Waldo read the paper of the evening on the Differential Diagnosis between Extrauterine Pregnancy and Early Abortion, after which a clinical conference on antipyretic treatment was held. A general discussion followed.

pyretic treatment was neid. A general discussion followed.
Changes of Address.—Dr. Carlos MacDonald, to 15
East Forty-eighth Street, New York.
Dr. Ross M. Bradley, from Boston, to 416 Main Street,
Jamestown, N. Y.
Dr. David Riesman, to 1715 Spruce Street, Philadelphia
Dr. Lewis Brinton, to 1913 Spruce Street, Philadelphia
Dr. H. M. Christian, to The Burlington, 1321 Spruce
Street Philadelphia Street, Philadelphia

Street, Philadelphia.

The Syracuse, N. Y., Academy of Medicine.—A regular meeting of this academy was held on Tuesday evening, October 27th. The programme included the following papers: Resection of the Knee Joint for Tuberculosis, by Dr. Nathan Jacobson; Report of a Case of Gunshot Wound of the Small Intestine, with presentation of the patient, by Dr. Frederick Flaherty; Report of a Case of Abdominal Pregnancy, by Dr. G. B. Broad.

The City Hornital at Atlantic City appounces the following the control of the patient of the

nancy, by Dr. G. B. Broad.

The City Hospital at Atlantic City announces the following changes in its staff: Dr. W. Blair Stewart has resigned as attending surgeon and will be succeeded by Dr. W. Price Davis; Dr. William M. Pollard has resigned as attending ophthalmologist and will be succeeded by Dr. W. L. Ridgeway; Dr. Charles K. Mills, of Philadelphia, has resigned as consulting neurologist and will be succeeded by Dr. T. D. Taggart, of Atlantic City.

Personal.—Dr. Smith Ely Jelliffe sailed for Europe results for a prolonged absence. Dr. Jelliffe will prosecute

cently, for a prolonged absence. Dr. Jelliffe will prosecute his psychiatric studies in various European cities. In consequence of the necessity of his remaining away from New York for a long time for that purpose, he has resigned his position as joint editor of the New York Medical Journal.

We are glad to be able to announce, however, that he has undertaken to favor us with frequent communications.

Contagious Diseases in Chicago.—During the week ending October 17, 1908, there were reported to the Department of Health 414 cases of contagious diseases, as follows: lows: Dipththeria, 132 cases; scarlet fever, 102 cases; measles, 9 cases; chickenpox, 5 cases; pneumonia, 24 cases; typhoid fever, 104 cases; whooping cough, 2 cases; tuberculosis, 31 cases; smallpox, 1 case; diseases of minor importance, 3 cases

Dr. Goldwater's Appointment.-On the application of the Board of Trustees of Bellevue and Allied Hospitals the Municipal Civil Service Commission of the city of New York has approved the appointment of Dr. S. S. Gold-water, superintendent of Mount Sinai Hospital, as a con-sulting expert in hospital administration and construction. to advise the architects and to supervise and direct the completion of the plans for the new Bellevue Hospital.

completion of the plans for the new Bellevue Hospital.

The Baltimore Medical Society.—The Section in Neurology and Psychiatry held a meeting on Friday evening, October 9th, and elected the following officers: Dr. Henry R. Dunton, of the Shepherd Hospital, president; Dr. I. J. Spear, secretary; Dr. E. C. Durrow, of Johns Hopkins, third member of the executive committee. Dr. Llewellys F. Barker read a paper on Psychology, and Dr. A. P. Herring read a paper on State Care of the Insane.

The Pathological Society of Philadelphia held a meeting on Friday evening, October 16th. The following papers were read: The Report of a Case of Metastatic Carcinoma of the Lung with Pathological Findings, by Dr. George W. Norris; A Brief Report of a Growth in the Testicle Resembling Sarcoma with Metastasis to the Lung, by Dr. J. Allison Scott; Congenital Nephritis, by Dr. Howard T. Karsner.

The South Boston Antituberculosis Society held a The South Boston Antituberculosis Society field a meeting on the evening of Thursday, October 1st, and elected the following officers for the ensuing year: President, Dr. Herbert J. Keenan; vice presidents, Dr. James S. MacDonald and Dr. William H. Ruddick; treasurer, Dr. Marcellus Reeves; secretary, Dr. Edward A. Tracy. The society is planning an educational campaign against tuberculosis and lectures and exhibits are being prepared

Civil Service Examinations .- Among the positions for which examinations will be held on November 21st by the New York State Civil Service Commission is that of second assistant physician to State Hospitals for the Insame. The salary is \$1,500 to \$2,000 per annum, with maintenance. The last day for filing applications is November 14th. Full information and application forms can be obtained by postal card request to the chief examiner of the commission, Mr. Charles S. Fowler, Albany.

Union County, N. J., Medical Society.-The one hundred and fiftieth regular meeting of this society was held on Wednesday afternoon, October 14th. The programme consisted of a "symposium" on the subject of tonsils and consisted of a Symposium on the Subject of tonsis and adenoids, and papers were read as follows: Symptomatology and Treatment, by Dr. William K. Simpson, of New York; Middle Ear Complications, by Dr. Norton L. Wilson, of Elizabeth, N. J.; Dangers and Accidents following Operations, by Dr. F. C. Ard, of Plainfield, N. J.

The College of Physicians of Philadelphia.--At a meeting of the Section in Ophthalmology, held on Thursday evening, October 15th, the programme included the following papers: Some Unusual Cases of Plastic Choroiditis, by Dr. G. E. de Schweinitz; Extensive Plastic Operation for Cicatricial Extropion of Both Eyelids, by Dr. William Zentmayer; Demonstration of a Case Showing on the Optic Nerve Head in Association with Pseudoneuritis. Dr. William Campbell Posey exhibited a patient showing an unusual inflammation of the cornea.

The Philadelphia Neurological Society.-At the regular meeting of this society, held on Friday evening, Oc tober 23d, the following papers were presented: Pseudo-bulbar Palsy, by Dr. James Hendrie Lloyd; A Case of Adiposis Dolorosa in which there is present Spasticity and Contracture Involving all the Extremities, by Dr. F. X. Contracture involving at the Extendities, by D.I. F. A. Dercum; Adiposis Dolorosa—A Consideration of its Diagnosis and Pathology, by Dr. G. E. Price; Report of a Case of Adiposis Dolorosa, by Dr. G. E. Price and Dr. H. Hudson; A Case of Adiposis Dolorosa with Involvement of the Large Nerve Trunks, by Dr. P. N. Bergeron.

Medical School Inspection in Chicago.-The medical inspectors of schools in Chicago examined 9,121 school children during the week ending October 17, 1908, and excluded 377 on account of contagious diseases. Physical examinations were made of 4,475 school children, and of this number 2,130 were advised to seek medical treatment. The defects found were as follows: Nutrition, 170; anæmia, 227; enlarged glands, 642; nervous diseases, 40; amemia, 227; emiarged glands, 042; nervous diseases, 40; cardiac diseases, 48; pulmonary diseases, 31; skin diseases, 92; orthopædic, 82; vision, 232; hearing, 142; nasal breath-ing, 232; palate, 12; teeth, 1,586; hypertrophied tonsils, 1,028; adenoids, 164; mentality, 51. During the week the chool nurse made 1,017 calls at the homes of school

The Associated Physicians of Long Island.—The thirty-second stated meeting of this society will be held to-day, at 3:75 p. m., at the Garden City Hotel, Garden City, L. I. The programme will include a paper on the Treatment of Fractures by Dr. James P. Warbasse, of Treatment of Fractures by Dr. James P. Warbasse, of Brooklyn, and a paper on the Treatment of Infantile Club Foot by Dr. Jaques C. Rushmore, of Brooklyn. The discussion will be opened by Dr. Algernon T. Bristow. The officers of the society are: President, Dr. H. Beeckman Delatour, of Brooklyn; first vice-president, Dr. Frank T. De Lano, of Rockville Centre; second vice-president, Dr. Frank Overton, of Patchogue; third vice-president, Dr. Thomas R. French, of Brooklyn; secretary, Dr. James Cole Hancock, of Brooklyn; treasurer, Dr. Charles B. Bacon, of Brooklyn; Brooklyn.

Charitable Bequests .- By the death of Ariel Lathrop, of Adamy, N. Y., the Albany Hospital becomes the absolute owner of \$50,000 left to the hospital by Mr. Lathrop several years ago on the condition that he was to have the income from it during his lifetime.

By the will of Louis Bourneuf, of Lynn, Mass., the Lynn

Hospital receives \$500. By the will of Mrs. Louise Breneman, the Ann C. Witmer Home for Aged Women, of Lancaster, Pa., receives

New York Academy of Medicine.-A stated meeting of the academy will be held on the evening of Thursday, November 5th, under the auspices of the Section in Surgery. The programme will include the following papers: Surgery of the Bile Passages, with Special Reference to End Results, by Dr. John C. Munro, of Boston; Treatment of Biliary Disease as Determined at the Operation, by Dr. Howard Lilienthal; Cholecystotomy versus Cholecystectomy, by Dr. John F. Erdmann.

on Thursday, November 19th, at 8:30 p. m., the anniversary address will be delivered by Major Charles Lynch, of the Medical Corps of the United States Army, on Medical Service in a Modern Army in War, as Exemplified by the Japanese Army in the Russo-Japanese War.

Medical Registration in Ohio.—The Ohio State Board

of Medical Registration and Examination has been informed that certain medical students, having preliminary educational requirements less than those required by the Ohio law, have been induced to attend medical colleges in other States, under the impression that, after graduation, they can return to Ohio and, under reciprocity, obtain a-license to practice in that State. This is erroneous. All medical students must understand that a license from another State is accepted in Ohio in place of an examination only. In all other particulars the applicant must comply with the laws of the State of Ohio and the rules of the State Board of Medical Registration and Examination, and the preliminary educational attainments must be equal to the requirements of Ohio colleges

Infectious Diseases in New York:

We are indebted to the Bureau of Records of the De-partment of Health for the following statistics of new cases and deaths reported for the two weeks ending October

| | | | Oct. 24- | |
|--------------------------|--------|---------|----------|--------|

New York Pathological Society.-At a meeting of this society, held on the evening of Wednesday, October 14th, Dr. Alfred Wolff-Eisner, of Berlin, read a paper entitled Theoretical and Practical Considerations concerning the Significance of the Conjunctival Reaction (Ophthalmothe Significance of the Conjunctival Reaction (Ophthalmotuberculin Test). Other papers read at this meeting were The Influence of Atoxyl on the Development of Syphilis in Lower Monkeys, by Dr. Simon Flexner; A Simple Method of Performing Serum Reactions, by Dr. Albert A. Epstein and Dr. Reuben Ottenberg; Bone Formation in the Kidney after Partial Extirpation, by Dr. Richard M. Pearce; Two-Unusual Forms of Sarcoma, by Dr. Leo Buerger; A Case of Typhoid Fever without Intestinal Lesions, associated with Cholelithiasis, Chronic Cholecystitis, and Multiple Hepatic Abscesses, by Dr. E. Martin.

The Eastern Medical Society of the City of New York.—At a stated meeting of this society, which was held on Friday evening, October 9th, Dr. Louis Fischer

held on Friday evening, October 9th, Dr. Louis Fischer demonstrated a new milk filter and milk cooling apparatus devised by Dr. Siegfried Weiss, of Vienna. Dr. Charles Goodman reported operations under local anæsthesia for thyreoidectomy for tumor of the thyreoid, and herniotomy for strangulated umbilical hernia. Dr. M. O. Magid read a paper entitled The Abuse of Medical Charity and its Remedy, which was discussed by Dr. S. S. Goldwater, Dr. S. F. Hallock, and Miss Lillian D. Wald. A paper on the Early Diagnosis of Cancer of the Stomach was read by Dr. Ludwig Kast, and among those who participated in the discussion of it were Dr. W. H. Thomson, Dr. Max Einhorn, Dr. Willy Meyer. Dr. G. A. Friedman, Dr. A. E. Isaacs, and Dr. Anthony Bassler.

The Sale of Deteriorated Food and Drugs by the Medical Department of the Army.—According to a statement by the Judge Advocate General of the Medical Department of the United States Army, the sale of deteriorated food and drugs is permissible in any State and at military posts or on reservations, transports, etc., it being held that Congress has no jurisdiction over such domestic sales. It is explained that as subsistence stores are presumed to be in proper condition upon their arrival at a military post and, in a majority of cases, become deteriorated while held in store, their sale, when so deteriorated, constitutes in a majority of cases a sale in State commerce in which the national food and drugs act would have no application. An order of the War Department would be operative if in furtherance of the pure food and drugs act, and not in conflict with State law.

Vital Statistics of New York .- During the week ending October 17, 1908, there were reported to the Department of Health of the City of New York 1,220 deaths from ail causes, of which 623 were in Manhattan, 122 in The Bronx, causes, of which 023 were in Manhattan, 122 in the Bloms, 367 in Brooklyn, 74 in Queens, and 34 in Richmond. The annual death rate in 1,000 of population was 14.17 in Manhattan, 19.43 in The Bronx, 12.82 in Brooklyn, 16.60 in Queens, 23.13 in Richmond, and in the whole city, 14.39. The death rate in the corresponding period in 1997 was 16.43. Of the total number of deaths 383 were of children under five years of age, of which 102 were due to diarrhœal diseases. There were 138 deaths from pulmonary tuberculosis during the week, as against 174 for the corresponding period in 1907. Deaths by violence numbered 88, of which 16 were suicides. There were 132 still births. Seven hundred and sixty-four marriages and 2,348 births were reported during the week.

Scientific Society Meetings in Philadelphia for the week Ending November 7, 1908:

Monday, November 2d.—Philadelphia Academy of Surgery; Biological and Miscroscopical Section, Academy of Natural Sciences; West Philadelphia Medial Association; Northwestern Medical Society.

Tuesday, November 3d.—Academy of Natural Sciences; Philadelphia Medical Examiners Association.

Wednesday, November 4th.—College of Physicians; Association and Chiladelphia Medical Examiners Association.

ciation of Clinical Assistants of Wills Hospital.
THURSDAY, November 5th.—Obstetrical Society; Medical Society of the Southern Dispensary; Section Meeting, Franklin Institute; Germantown Branch, Philadelphia County Medical Society; Southeastern Medical Society;

ciety.
FRIDAY, November 6th.—American Philosophical Society;
Kensington Branch, Philadelphia County Medical So-

The Mortality of Chicago.—There were reported to the Department of Health of the City of Chicago 550 deaths from all causes during the week ending October 17, 1908. as compared with 503 for the preceding week and 508 for the corresponding period in 1907. The annual death rate in 1,000 of population was 13.25, as against a death rate of 12.10 for the preceding week. The principal causes of death were: Apoplexy, 13 deaths; Bright's disease, 45 deaths; bronchitis, 10 deaths; consumption, 70 deaths; cancer, 24 deaths; diphtheria, 18 deaths; heart diseases, 43 deaths; influenza, 2 deaths; intestinal diseases, acute, 77 deaths; and the procedure of deaths. deaths; measles, I death; messinal useases, active, year deaths; measles, I death; pneumonia, 48 deaths; scarlet fever, 2 deaths; suicide, II deaths; typhoid fever, I0 deaths; violence, other than suicide, 38 deaths; whooping cough, 3 deaths; all other causes, II0 deaths. Of the total number of deaths II8 were of children under one year of age and 46 between one and five years of age.

Labor Unions and Tuberculosis.-At a recent meeting of the State Federation of Labor, held in Rochester, N. Y., the following resolutions were introduced:

Resolved, To endose the campaign conducted by the State Charities Aid Association and the State Department of Health for the prevention of tuberculosis and recommending that all central and local bodies cooperate and render all possible assistance, and To commend the Albany Federation of Labor for the establishment of a tuberculosis pavilion and recommending that all central bodies foriow the example sent by Albany

An address was delivered by Mr. Philip V. Danahy president of the board of governors of the Albany Pavilion, on the subject of tuberculosis, in which he told of measures employed to arrest the spread of the disease, and of the efforts of the labor people in Albany toward the

erection of the pavilion. The delegates from Brooklyn were particularly interested, as the Brooklyn Central Labor Union purchased sixty acres of land some time ago for the establishment of a tuberculosis hospital, but have been unable to go on with the project on account of lack of

The Harvey Society Lectures.—The first lecture of the fourth course of the Harvey Society Lectures was delivered on Saturday evening, October 24th, by Professor A. Calmette, of the Institut Pasteur de Lille, France, on Intestinal Infection and Immunity in Tuberculosis. The other lectures of the course are as follows: Fever, by Professor W. G. MacCallum, of Johns Hopkins University, on November 7th; Metabolism in Diabetes, by Professor Graham Lusk, of the University and Bellevue Hospital Medical Colleges on November 1sts. Therapeutics of Diabetes by ham Lusk, of the University and Believue riospital Medical College, on November 21st; Therapeutics of Diabetes, by Dr. Wilhelm Falta, of the University of Vienna, on November 28th; Anaphylaxis, by Dr. M. J. Rosenau and Dr. John F. Anderson, of the U. S. Public Health and Marine Hospital Service, on December 5th; Osmosis, by Professor A. B. Macallum, of the University of Toronto, on December 5th; December 5th; Osmosis, by Professor A. B. Macallum, of the University of Toronto, on December 5th; Osmosis, by Professor A. B. Macallum, of the University of Toronto, on December 5th; Osmosis, by Professor A. B. Macallum, of the University of Toronto, on December 5th; Osmosis, by Professor A. B. Macallum, of the University of Toronto, on December 5th; Osmosis, by Professor A. B. Macallum, of the University of Toronto, on December 5th; Osmosis, by Professor A. B. Macallum, of the University of Toronto, on December 5th; Osmosis, by Professor A. B. Macallum, of the University of Toronto, on December 5th; Osmosis, by Professor A. B. Macallum, of the University of Toronto, on December 5th; Osmosis, by Professor A. B. Macallum, of the University of Toronto, on December 5th; Osmosis, by Professor A. B. Macallum, of the University of Toronto, on December 5th; Osmosis, by Professor A. B. Macallum, of the University of Toronto, on December 5th; Osmosis, by Professor A. B. Macallum, of the University of Toronto, on December 5th; Osmosis, by Professor A. B. Macallum, of the University of Toronto, on December 5th; Osmosis, by Professor A. B. Macallum, of the University of Toronto, on December 5th; Osmosis, by Professor A. B. Macallum, of the University of Toronto, on December 5th; Osmosis, by Professor A. B. Macallum, of the University of Toronto, on December 5th; Osmosis, by Professor A. B. Macallum, of the University of Toronto, on December 5th; Osmosis, by Profes A. B. Macallum, of the University of Toronto, on December 19th; The Relation of the Liver to the Metabolism of Fat, by Professor J. B. Leathes, of the Lister Institute of Preventive Medicine, England, on January 9, 1909; Some Problems in Immunity and the Treatment of Infectious Diseases, by Professor Philip Hanson Hiss, of Columbia University, on February 6, 1909; Heredity in Man, by Professor C. B. Davenport, of Cold Spring Harbor Station for Experimental Evolution, on March 6, 1909.

Nociety Meetings for the Coming Week:
Monday, November 2d.—German Medical Society of the City of New York; Utica, N. Y., Medical Library Association; Niagara Falls, N. Y., Academy of Medicine; Practitioners' Club, Newark, N. J.; Hartford, Conn., Medical Society.

Medical Society.

Tuespay, November 3d.—New York Academy of Medicine
(Section in Dermatology); New York Neurological
Society; Buffalo Academy of Medicine (Section in
Surgery); Ogdensburgh, N. Y., Medical Association;
Syracuse, N. Y., Academy of Medicine; Hudson
County, N. J., Medical Association (Jersey City);
Medical Association of Troy and Vicinity; Hornellsville, N. Y., Medical and Surgical Association; Long
Island, N. Y., Medical Society; Bridgeport, Conn.,
Medical Association Medical Association.

Medical Association.

Wednesday, November 4th.—Society of Alumni of Bellevue Hospital, New York; Harlem Medical Association, New York; Elmira, N. Y., Academy of Medicine; Psychiatrical Society of New York.

Thursday, November 5th.—New York Academy of Medicine: Dansville, N. Y., Medical Association.

Friday, November 6th.—New York Academy of Medicine (Section in Surgery); New York Microscopical Society; Gynæcological Society, Brooklyn, N. Y.; Manhattan Clinical Society, New York; Practitioners' Society of New York. ciety of New York.

The Health of Pittsburgh .- During the week ending September 19th the following cases of transmissible diseases were reported to the Bureau of Health of Pittsburgh: Chickenpox, I case, 0 deaths; typhoid fever, 30 cases, 2 deaths; scarlet fever, 25 cases, 4 deaths; diphtheria, 15 cases, 3 deaths; measles, 6 cases, 0 deaths; whooping cough, 4 cases, 0 deaths; pulmonary tuberculosis, 24 cases, 10 deaths. The total deaths facilities for the case of the c ro deaths. The total deaths for the week numbered 147, in an estimated population of 565,000, corresponding to an annual death rate of 13.54 in 1,000 of population. the week ending September 26th, the following cases of transmissible diseases were reported: Chickenpox, I case, o deaths; typhoid fever, 27 cases, 5 deaths; scarlet fever, 40 cases, 1 death; diphtheria, 26 cases, 2 deaths; measles, 5 cases, o deaths; whoopingcough, 3 cases, I deaths; pul-monary tuberculosis, 15 cases, 9 deaths. The total deaths for the week numbered 170, corresponding to an annual death research. death rate of 15.64 in 1,000 of population. During the week ending October 3d the following cases of transmissible diseases were reported: Chickenpox, I case, o deaths; typhoid fever, 15 cases, 4 deaths; scarlet fever, 27 cases, 2 deaths; diphtheria, 17 cases, 2 deaths; measles, 8 cases, 0 deaths; whooping cough, 3 cases, I death; pulmonary tuberculosis, 12 cases, 10 deaths. The total deaths for the week numbered 133, corresponding to an annual death rate of 12.23 in 1,000 of population. During the month of July there were 719 deaths in the city, corresponding to an annual death rate of 15.25 in 1,000 of population.

THE BOOKS OF SIX MONTHS

THE PRINCIPAL MEDICAL BOOKS PUBLISHED SINCE APRIL 1, 1908

Nearly all the medical books that have been issued by American publishers during the year, as well as many others, of foreign production, have already been reviewed in our columns. These reviews, however, are scattered throughout the different numbers of the Journal for the entire year, and are consequently not easily accessible to the reader. We feel confident, therefore, that our readers will find that the list which we have compiled here below will be of great value as a guide to the selection of books for the library. In view of the fact that the majority of the books have already received review notice, we insert only occasional brief comments. For convenience of reference, the titles of the publishing houses are arranged alphabetically.

D. APPLETON & COMPANY, New York.

LEXER.—General Surgery. By EHRICH LEXER, M. D., Professor of Surgery, University of Königsberg; translated by Dean Lewis, M. D., Assistant Professor of Surgery, Rush Medical College, and edited by Arhhur Dean Bevan, M. D., Professor and Head of the Department of Surgery, Rush Medical College. Published July 29, 1908; 450 Illustrations, Five Colored Plates. 1,041 pages. Price, cloth, \$6.00, and half leather, \$7.00. It is a presentation of the scientific principles upon which the practice of surgery is based.

P. BLAKISTON'S SON & COMPANY, Philadelphia.

Beasley.—Book of Prescriptions. Containing a Complete Set of Prescriptions Illustrating the Employment of the Materia Medica in General Use; Comprising also Notes on the Pharmacology and Therapeutics of the Principal Drugs and the Doses of their Preparations Principal Drugs and the Doses of their Preparations
According to the Imperial and Metric Systems, with an
Index of Diseases and Remedies. By Henry Beasley.
Ninth Edition, rewritten by E. W. Lucas, F. I. C.,
F. C. S. With an Introduction by Arthur Latham,
M. D. 16mo; 366 pages. Price, cloth, \$2.00.
Brubaker.—Textbook of Physiology. Specially adapted
for the use of Students. Including a Section on Physiological Apparatus. By A. B. Brubaker, M. D., Professor of Physiology and Hygiene at Jefferson Medical
College: Professor of Physiology. Pennsylvania Col-

College; Professor of Physiology, Pennsylvania College of Dental Surgery, Philadelphia. With an appenlege of Dental Surgery, Philadelphia. With an appendix giving a brief account of some essential forms of apparatus suited to those who have not large laboratory opportunities. Third Edition, thoroughly Revised and in Parts Rewritten. Colored Plates and 383 other Illustrations. 8vo; xii, 752 pages. Price, cloth, \$3.00.

CLOWES.—A Treatise on Qualitative Analysis and Practical Chemistry. Adapted for Use in the Laboratories of Colleges and Schools. By Frank Clowes, D. Sc., F. I. C. Eighth Edition, Revised. Illustrated. 1200.

DUFF.—A Textbook of Physics. By Various Writers. Edited by A. WILMER DUFF, A. M., Sc. D., Professor of Physics, Worcester Polytechnic Institute, Worcester, Mass. With 511 Illustrations. Small 8vo; xi, 680 pages. Price, cloth, \$2.75.

pages. Price, cloth, \$2.75

The preparation of a work of this grade by the collaboration of several writers is a somewhat novel undertaking. It represents the attempt of seven experienced teachers of college physics to prepare a textbook that would be more satisfactory to all of them than an existing one, the idea being, of course, that such a book would also prove acceptable to other teachers. It seems that there is a need, and there must be a place, for a work prepared in this EDWARDS.—Diseases of the Rectum, Anus, and Sigmoid Colon. By E. SWINFORD EDWARDS, F. R. C. S. Being the third edition of Cooper and Edwards' Diseases of the Rectum and Anus. Illustrated and Enlarged. 8vo; xii, 442 pages. Price, cloth, \$4.20.

EMERY.—Clinical Bacteriology and Hamatology for Practitioners. By W. D'ESTE EMERY, M. D., B. Sc. (Lond.), Clinical Pathologist to King's College Hospital, and Pathologist to the Children's Hospital, Paddington Green; formerly Assistant Bacteriologist to the Royal Colleges of Physicians and Surgeons, and some-time Lecturer on Pathology and Bacteriology in the University of Birmingham. Third Edition, Revised. University of Birmingham. Third Edition, Revised.
With 10 Plates containing 62 Figures, some in Colors.
and 52 other Illustrations. 8vo; xxxv, 252 pages. Price, cloth, \$2.00.

GOULD.—Borderland Studies. Vol. II. Miscellaneous Addresses and Essays pertaining to Medicine and the Medical Profession and their Relation to General Science and Thought. By George M. Gould, A. M., M. D. 48 Illustrations. 12mo; 311 pages. Price, cloth, \$1.50.

It is eight years since the first volume of this series appeared, but the various addresses and essays have so little connection among themselves that this volume is quite as readable without its predecessor as it would be with it.

Grimshaw.—Your Child's Health. By John Grimshaw. M. D., B. S., D. P. H., M. R. C. S. With an Introduction by Sir James Barr. 8vo; 144 pages. Price,

A collection of medical notes for mothers, nurses, and teachers, telling what to do in the simple emergencies affecting health in child life.

Haig.—Causation of Disease by Uric Acid. A Contribution to the Pathology of High Arterial Tension, Headache, Epilepsy, Mental Depression, Gout, Rheumatism, Diabetes, Bright's Disease, Anæmia, etc. By Alexanper IIAig, M. A., M. D. (Oxon.), F. R. C. P., Physician to Metropolitan Hospital, London. 75 Illustrations. Seventh Edition, thoroughly Revised. 8vo; 940 pages. Price, cloth, \$4.00.

halliburton.—Kirbes' Physiology. Revised and Enlarged by W. D. Halliburton, M. D., F. R. S., Professor of Physiology, King's College, London. Twenty-first Edi-tion. With 677 Illustrations, a number of which are printed in Colors. 12mo; xvii, 916 pages. Price, cloth, \$3.00; leather, \$3.75.

ASJOS; Realter, 43.75.

HARDESTY.—A Laboratory Guide for Histology. Laboratory Outlines for the Study of Histology and Microscopic Anatomy. By IRVING HARDESTY, A. B., Ph. D., Associate Professor of Anatomy in the University of California. With a Chapter on Laboratory Drawing by ADELEBERT WATTS LEE, M. D., Assistant in Anatomy in the University of California. With 30 Illustrations, 2 of which are in Color. 8vo; vii, 193 pages. Price, and the Color of the Co cloth, \$1.50.

JELLETT.—A Short Practice of Midwifery for Nurses. By HENRY JELLETT, B. A., M. D., F. R. C. P. I., Gynæcologist and Obstetrical Physician to Dr. Stevens' Hospital, Dublin. Third Edition, Revised. With 6 Plates and 164 other Illustrations, together with an Appendix and Glossary. 12mo; xiv, 463 pages. Price, cloth, \$2.00.

JELLETT.—A Short Practice of Midwifery. By HENRY JELLETT, B. A., M. D., F. R. C. P. I. With a preface by Sir W. J. SMYLY, M. D., F. R. C. P. I. Fifth Edition, Revised. With 200 Illustrations. 12mo, xx, 654

pages. Price, cloth, \$4.20.

Johnson.—A Textbook of Operative Dentistry. By Various Authors. Edited by C. N. Johnson, M. A., L. D. S., D. D. S., Professor of Operative Dentistry in the Chicago College of Dental Surgery; Editor of The Dental Review. With 618 Illustrations. 8vo; 762 pages. Price, cloth, \$6.00; sheep, \$7.00.

The object of this book is to provide a textbook giving the most approved and latest methods employed by the foremost thinkers and teachers of the dental profession. The contributors have been selected with regard to their special fitness and ability to write upon the subjects assigned. A stronger syndicate of well known men could not easily be brought together. The book contains much new material of great practical and permanent value.

Lee.—Experimental Chemistry. A Textbook of (with Descriptive Notes), for Students of General Inorganic Chemistry. By Edwin Lee, Professor of Chemistry in Allegheny College, Meadville, Pa. With 57 Illustrations. 12mo, 433 pages. Price, cloth, \$1.50.

MAYLARD.—Abdominal Tuberculosis. By A. ERNEST MAYLARD.—Bon, M. B., B. S. (Lond.), Surgeon to the Victoria Infirmary, Glasgow, late Examiner in Surgery to the University of Glasgow. With 57 Illustrations. 8vo; xvi, 360 pages. Price, cloth, \$4.00.

"Fifty-one clinical histories of illustrative cases are introduced. The work is to be commended as a substantial addition to our literature of the subjects with which it deals."-New York Medical Journal.

Meller.—Ophthalmic Surgery. A Handbook of the Surgical Operations on the Eyeball and its Appendages, as Practised at the Clinic of Hofrat Prof. Fuchs. By Dr. Practised at the Clinic of Hofrat Prof. Fuchs. By Dr. Josef Meller, Privatdocent and First Assistant K. K. II University Eye Clinic, Vienna. The Translation reviewed by Walter L. Pyle, A. M., M. D., Member of the American Ophthalmological Society; Fellow of the College of Physicians of Philadelphia; Ophthalmologist to the Mt. Sinai Hospital, etc. With 118 original Illustrations, 7 of which are in Color. 8vo; xiii, 262 pages. Price cloth \$300. Price, cloth, \$3.00.

This work is not a translation of a German publication, but a careful rendering in English of Dr. Meller's original manuscript, and has not as yet ap-

peared in German.

MEMMINGER.—Diagnosis by the Urine. The Practical Examination of Urine, with Special Reference to Diagnosis. By Allard Memminger, M. D., Professor of Chemistry and Hygiene; Clinical Professor of Urinary Diagnosis in the Medical College of the State of South Carolina, etc. Third Edition, Enlarged and Revised. 27 Illustrations. 12mo, xi, 116 pages. Price, cloth.

MURRAY.—Hernia: Its Cause and Treatment. By R. W. MURRAY. With 27 Illustrations. 8vo; 99 pages. Price,

"The book is a valuable one in view of the novelty of the theories presented, and is worthy of a careful perusal."-Journal of the American Medical Asso-

SLUSS.—Manual of Emergency Surgery. By JOHN W. SLUSS. M. D., Professor of Anatomy and Clinical Surgery Medical Department of Pardue University, Indianapolis. 584 Illustrations. xii, 677. Price, full limp leather, gilt edges, round corners, \$3.50.

This is a surgery for the general practitioner, intended to serve as a guide out of uncertainty in time of distress. The aim has been to make it practical above all things. Theoretical discussions are denied any place. Beginning with the general practitioner as an emergency surgeon, his duties, responsibility and equipment, the book takes the reader through emergency antisepsis, anæsthesia, sutures, drainage, dressings, shock, hæmorrhage, wounds, fractures, injuries, abscess, phlegmon, osteomyelitis, septic arthritis, foreign bodies, burns, scalds, frost bite. tracheotomy, laryngotomy, œsophagotomy, thoracotomy, empyema, craniectomy, mastoid abscess, laparotomy for traumatism, appendicular inflammation, peritonitis, acute intestinal obstruction, artificial anus, hernia, enterectomy, torsion of the pedicle, tubal gestation, Cæsarean section, urethra, arteries, amputations, dilations, phimosis, paraphimosis, circumcision, hydrocele, castration, ingrowing nails, removal of tumors, and skin grafting.

STEWART.—Compend of Pharmacy. Based upon Remington's Textbook of Pharmacy. By F. E. STEWART, M. D., Ph. G., late Quiz-Master in Chemistry and Theoretical Pharmacy, Philadelphia College of Pharmacy. Lecturer on Pharmacology, Jefferson Medical College. Seventh Edition, Revised in accordance with the latest Edition of the U. S. P., conforming with the new Food and Drug Act. Complete Tables of Metric and English Weights and Measures. Blakiston's Quiz Compend Series. Price, cloth, \$1.00; interleaved for the addition of notes. \$1.25.

addition of notes, \$1.25.

TAYLOR.—Manual of the Practice of Medicine. By Frederick TAYLOR, M. D., F. R. C. P. Eighth Edition, Revised. With 8 Plates and 46 Figures. 8vo; 1,111 pages.

Price, cloth, \$6.40.

Tyrope.—Pharmacology. The Action and Uses of Drugs.
By MAURICE VEJUX Tyrope, M. D., Instructor of Pharmacology in the Medical School of Harvard University. 8vo; 255 pages. Price, cloth, \$1.50.

"This little book has been prepared on an excellent plan, drugs being grouped according to their principal therapeutic actions, and each group designated by the name of the most prominent drug contained in it. The information given is necessarily condensed, but the work does not purport to be exhaustive."-New York Medical Journal.

WILLIAMS.—Manual of Bacteriology. By Herbert U. WILLIAMS, M. D., Professor of Pathology and Bacteriology, Medical Department, University of Buffalo. Fifth Edition, Revised and Enlarged by R. Meade Bolton, M. D., Expert, Bureau of Animal Industry, Washington. Fourth Edition. With 113 Illustrations 12mo; xiii, 466 pages. Price, cloth, \$2.00.

THE CLINIC PUBLISHING COMPANY, Chicago.

King.—Stories of a Country Doctor. By Willis P. King, M. D., First Vice-President of American Medical Association, etc. Pp. 322.

BUTLER.—The Exploits of a Physician Detective. By George F. Butler, M. D., Professor and Head of the Department of Therapeutics and Professor of Clinical Medicine Chilego College of Medicine and Surgery. Medicine, Chicago College of Medicine and Surgery. Pp. 398.

THE GRAFTON PRESS, New York.

Kolle.—Subcutaneous Hydrocarbon Protheses. By F. Strange Kolle, M. D. Square 8vo. Illustrated. Price, cloth, \$2.50.

This is a comprehensive and concise treatise on the use of subcutaneous injections of hydrocarbon

for the correction of defects about the face, neck, and shoulders—a book that should be in the library of every up to date physician in the world. It is based on the personal experience of a practical surgeon specialist, together with an extensive reference to all the leading authorities.

W. T. KEENER & COMPANY, Chicago.

Compton.—Essentials of Surgery. An Outline of Surgical Pathology, Diagnosis and Treatment. By Alwyne T. Compton, F. R. S. C., 12mo., 439 pages, 77 Engravings and 27 Half Tones. Price, cloth, \$1.50.

much enlarged. With 174 Illustrations and o Full Page Plates. 8vo; 625 pages. Price, cloth, \$3.75.
Water and Continuing of the Gentlourinary System. By Francis S. Watson, M. D., Senior Visiting Surgeon at the Boston City Hospital, Lecturer on Genitourinary Surgery in the Harvard Medical School, and John H. Cunningham, M. D., of Boston, Member of the American Association of Genitourinary Surgeons. With about 500 Engravings

and 42 Full Page Colored Plates, mostly from Original Drawings. In two very handsome octavo volumes of about 1100 pages.

Diseases of the male half of the human race constitute a very broad department of surgery and one which has been notably progressive, particularly in late years. The whole subject is presented in this new work in its ripest development and by recognized leaders. Both the medical and surgical aspects has been fully covered. The elaborate series of engravings and colored plates are of the highest merit and mostly from original drawings. They have been specially prepared to exhibit diagnostic and practical points, including even the steps of operations. The importance of this work and the beauty of its illustrations have led the publishers to give it a sumptuous form.

WOOLSEY.—Applied Surgical Anatomy Regionally Presented. For the use of Students and Practitioners of Medicine. By George Woolsey, A. B., M. D., Professor of Anatomy and Clinical Surgery in Cornell University Medical College, New York. New (2d) edition, thoroughly revised. With 200 Illustrations in Black and Colors. In one very handsome octavo vol-

ume of about 600 pages.

LONGMANS, GREEN, & COMPANY, New York.

The Proceedings of the Royal Society of Medicine. Volume 1. No. 6. Large square 8vo. Price, \$2.00; annual subscription, \$16.00. The proceedings will be published monthly, from

November to July inclusive

SCHAEFER AND OTHERS.—Quain's Elements of Anatomy.
Edited by Edward Albert Schaefer, F. R. S., Professor of Physiology and Histology in the University of Edinburgh; JOHNSON SYMINGTON, M. D., F. R. S., Professor of Anatomy in Queen's College, Belfast; and rrotessor of Anatomy in Queen's College, Belfast; and Thomas Hasen Baye, M. A. M. D. Lecturer in Anatomy, University of Glasgow. Vol. I. Embrylogy. By T. H. Bryce, M. A., M. D. Illustrated by more than 300 Engravings, many of which are colored. Royal 8vo; viii, 276 pages. Price, \$3.00.

The remaining volumes will comprise respectively: General and visceral anatomy; the nervous system and sense organs; and the bones, ligaments, muscles, and bloodvessels. Each volume will be complete in itself and will serve as a textbook for the particular subject or subjects with which it deals. The work has been completely reedited and brought up to date. The volume on Embryology, which was written for the previous edition by Professor Schäfer, has in the present edition been entrusted to Dr. Bryce, who has rewritten it and has added a large number of illustrations. The advances in our knowledge of human embryology have necessitated considerable additions to the text, and this, combined with the profuseness of illustration, has resulted in some increase in bulk of the volume.

WILSON AND HOWELL—Movable Kidney. Its Pathology, Symptoms, and Treatment. By Harold W. Wilson, M. B., B. S. (Lond.), F. R. C. S. (Eng.). Demonstrator of Anatomy and Chief Assistant in the Surgical Out Patient Department, St. Bartholomew's Hospital; late Luther Holden Research Scholar; and C. M. Hinder Holden, Research Scholar; and C. M. Hinder Holden, S. B. Ch. (Oxon), M. R. C. P. (Lond.), Junior Demonstrator of Physiology, late Casualty Physician, St. Bartholomew's Hospital; Pathologist, late Registrar to National Hospital for the Paralyzed and Epileptic. Svo, viii, 104 pages. Price, Paralyzed and Epileptic. 8vo, viii, 104 pages. Price,

\$1.25.

An attempt has been made in this book to give a concise account of the various conditions included under the term movable kidney. The experimental pathology described was undertaken by one of the authors when holding the Luther Holden Research Scholarship at St. Bartholomew's Hospital. The results of the experiments have, however, been critically examined by both.

THE MACMILLAN COMPANY. New York.

BRYCE, TEACHER, AND KERR—Contributions to the Study of the Early Development and Imbedding of the Human Orum. I. An Early Ovum Imbedding in the Decidua. By THOMAS H. BRYCE, M. A., M. D., and JOHN H. WILLIAM WOOD & COMPANY, New York.

BRYANT AND BUCK.—American Practice of Surgery. A Complete System by Representative Surgeons of the United States and Canada. Edited by Joseph Decature BRYANT, M. D., and Albert Henry Buck, M. D. To BRYANT, M. D., and ALBERT HENRY BUCK, M. D. 10 be Published in Eight Royal Octavo Volumes, Illustrated by Chromo Lithographic and other Plates and by Line and Half Tone Engravings. Volume IV. Profusely Illustrated by Engravings in the Text and 2 Colored Plates. Royal 8vo; 1050 pages. Price, muslin, \$7.00; leather, \$8.00; half morocco, \$9.00.

This monument to American eminence in surgery more than fulfills the promise of the earlier volumes. As the work progresses and reaches the more specialized topics, the wisdom of the editorial choice

of authors, and the excellence of the supervision and editorial work, become more noticeable than ever. In the present volume, the articles on dislocations, congenital dislocations, contraindications to operating, the preparations for an operation, the care of the patient during and immediately after the operation, anæsthetics, amputations, excisions and resections, minor surgery and bandaging, plastic surgery, and tuberculous diseases of the spinal column may be mentioned as especially valuable. The mechanical make up is beautiful, the illustrations numerous and excellent, and the magnitude of the undertaking and value of the work when completed may be realized when we consider that there are to be eight of these volumes.

STEDMAN.-Appendix to the Reference Handbook of the Medical Sciences. Revised to Date. Edited by Thomas L. Stepman, A. M., M. D. 4to, 680 pages. Profusely Illustrated. Price, muslin, \$5.00; leather, \$6.00; half morocco, \$7.00. (Sold only by subscription.)

Axenfeld.—The Bacteriology of the Eye. By Dr. Theo-ENFELD.—In Bacteriology of the Eye. By Dr. Theo-por Anexpred.p. Professor of Ophthalmology in the University of Freiburg. Translated by Augus Mac-NAB, B. A., B. Sc., M. B., Ch. B., F. R. C. S., Chief Clinical Assistant, Royal London Ophthalmic Hos-pital. Illustrated by 3 Chromolithographic Plates, and Engravings in Black and Colors. Royal 8vo; 418 pages. Price, muslin, \$6.00.

This work is not intended for the professional bacteriologist, but rather for the progressive physician who wishes, whether for the purpose of clinical diagnosis of for the use in the study of the ætiology of this class of diseases, to familiarize himself with the bacterial aspect of the subject. The work seems to be very complete, including tables to assist in the determination of the findings by microscopical examination.

BARUCH.-The Principles and Practice of Hydrotherapy. A Guide to the Application of Water in Disease, for Students and Practitioners of Medicine. By SIMON BARUCH, M. D., Professor of Hydrotherapy in Columbia University (College of Physicians and Surgeons), New York, etc. Third Revised Edition. Profusely Illustrated, and with a complete Index. 8vo; 556

pages. Price, extra muslin binding, \$4.00.

BROOKE.—Aids to Tropical Medicine. By GILBERT E.

BROOKE. Charts and a Plate. 16mo; 175 pages. Price,

This volume, in the well known "Students' Aids Series," is a good epitome of a subject which is daily acquiring more importance. It can be recommended to any one desiring a work of this sort.

CALMETTE.—Venoms. Venomous Animals and Antivenomous Serum Therapeutics. By A. CALMETTE, M. D. Translated by Ernest E. Austin, F. Z. S. Profusely Illustrated. 4to. Price, muslin, \$5.00.

One of the most brilliant results in the field of serum therapeutics was the discovery of antivénéne by Calmette, some fifteen years ago, almost immediately after the work of Roux and Behring with reference to toxines of diphtheria and tetanus. For the last fifteen years Professor Calmette has been occupied continuously with the subject of snake poison, and a great number of memoirs on venoins and the various venomous animals, and on antivenomous serum therapeutics, have been published by him and by his students. The present work is a resume of the results to date, and will be welcomed by all desiring practical instruction in such matters, as well as by workers in the general field of antitoxines. book is beautifuly illustrated, printed, and bound.

Being a Series of CLAIBORNE.—Cataract Extraction. Papers with Discussion and Comments Read before the Ophthalmological Section of the New York Acaden:y of Medicine. Edited by J. Herbert Claiborne. Illustrated. 8vo. Price, extra muslin, \$2.00.

In this work it seems as though the last word had been said for our present knowledge of cataract extraction. It is especially valuable as being the presentation of the subject by numerous authorities, and the discussions, with the editor's coments, give harmony to the whole. In its mechanical make up it is

a veritable edition-de-luxe.

DANA.—Testbook of Nervous Diseases and Psychiatry.

For the Use of Students and Practitioners of Medicine. By CHARLES L. DANA, A. M., M. D., L.L.D.,
Professor of Nervous Diseases in Cornell University
Medical College; Visiting Physician to Bellevue Hospital; Neurologist to the Montefore Hos ogist to the Woman's Hospital; Consulting Physician to the Manhattan State Hospital. Seventh Edition. Completely Revised and Entirely Reset. Profusely Illustrated by 261 Engravings in Black and Colors, and 3 Plates. 8vo; 794 pages. Price, extra muslin, \$5.00; leather, \$6.00.

Freyer.—Clinical Lectures on the Surgical Diseases of the Urinary Organs. By P. J. Freyer, M. A., M. D., M. Ch. Illustrated. 8vo; 433 pages. Price, extra

muslin, \$4.00.

Dr. Freyer is a well known figure in the world of genitourinary surgery, and the present volume, based upon his lectures, will command universal attention. The aim of this book is to give a clear, concise, and practical résumé of our most recent knowledge of the subject dealt with, the methods of treatment advocated being those which the author has found sound and effective.

HARMAN.—Aids to Ophthalmology. By N. BISHOP HARMAN. Fourth Edition. Illustrated. 16mo; 170 pages.

Price, muslin, \$1.00.

Herman.—The Student's Handbook of Gynæcology. By George Ernest Herman, M. B., F. R. C. P., etc. Il-lustrated. 12mo; 560 pages. Price, extra muslin, \$2.50.

Mr. Herman is a prolific writer and is well known through his larger work, Diseases of Women, and perhaps even better for his small work on Difficult Labor. The present volume epitomizes the complicated subject of gynæcology in a most convenient

fashion.

Hutchison.—An Index of Treatment. By Seventy-two Writers. Edited by ROBERT HUTCHISON, M. D., F. R. C. P., Physician to London Hospital and Assistant Physician to Hospital for Sick Children, Great Ormond Street, and H. Stansfield Collere, F. R. C. S., Surgeon to St. Mary's Hospital; Joint Lecturer on Surgery in St. Mary's Hospital; Joint Lecturer on geon to the Hospital for Sick Children. Revised and Edited to Conform with American Practice by Warren Collegan, M. D., Professor of Clinical Medicine and Instructor in Therapeutics, Cornell University Medical College; Visiting Physician to Bellevue Hospital, New York. Illustrated. 8vo; 903 pages. Price, muslin binding, \$6.00; half morocco, \$7.00. P., Physician to London Hospital and Assistant

This work is something of a novelty, in that it embraces practically the whole field of medicine in a concise and practical manner, with each topic treated by a separate writer of well known authority in his subject. There are seventy-two of these writers, and their names, for which, unfortunately, space is lacking here, are a sufficient guarantee of the value of the contributions. The work is meant to provide the practising physician with a complete and convenient guide to treatment, within a moderate compass. The practical usefulness and availability for ready reference has been especially kept in mind. We understand that in England the large edition was exhausted within about two months of pub-

lication, and the astonishing statement has been made that nearly half of the physicians in the United Kingdom purchased the book. The editorial supervision, by Robert Hutchison, seems to have been conducted with the ability one would expect from a man of his experience and reputation. This American edition has been thoroughly revised and edited by Dr. Coleman to conform in all respects with American practice where it differs from practice in England. In the matter of doses, drugs, and animal extracts especially, there is a considerable difference in practice, and these have been carefully substituted. Every practising physician should possess one of these books.

KERR.—Operative Midwifery. By J. N. Munro Kerr, M. B., C. M., Glas. Obstetric Physician, Glasgow Maternity Hospital; Gynæcologist, Western Infirmary, etc., Profusely Illustrated by 293 Engravings. 8vo;

717 pages. Price, muslin, \$6.00.

Munro Kerr is sufficiently well known to all English speaking physicians to command respect for anything from his pen, and this new work entirely justifies one's expectations. As the author remarks in his preface: "The art of midwifery can no longer be considered a subdivision of medicine, but must be regarded as a branch of surgery requiring a thorough knowledge of surgical principles." To the operating obstetrician this book will especially appeal, while to the practitioner, who must realize, perhaps, even more than the operator, the indications and bearing of an operation, it will prove almost equally valuable. The style is clear and concise and essentially practical. The work is beautifully illustrated and finely printed on excellent paper.

Leedham-Green.—The Treatment of Gonorrhaa in the Male. By Charles Leedham-Green, M. B., F. R. C. S. Second Edition. Illustrated. 8vo; 172 pages.

C. S. Second Edition. Infustrated. Svo; 172 pages.
Price, extra muslin, \$2.00.
M'Lachlan.—Applied Anatomy. Surgical, Medical, and
Operative. By John M'Lachlan, M. D., F. R. C. S.
Revised and Largely Rewritten by A. A. Scott Skirving, C. M. G., F. R. S. C. Fourth Edition. Illustrated.
Large 12mo; 1000 pages. Price, extra muslin, \$6.00.
MAISONNEUVE.—The Experimental Prophylaxis of Syphilis.
By Do Part Marcon Neury. Corporate the Sender

AISONNEUVE.— The Experimental Prophylaxis of Syphilis. By Dr. PAUL MAISONNEUVE. Containing the Results of the Experiments on the Subject Carried Out at the Pasteur Institute, by Professors Metchnikoff and Roux. Translated, and with an Introduction by Fernand S. De Vertenil, M. B., M. R. C. S., Surgeon R. N. Izmo. Price, extra muslin, \$1.50.

The remarkable discovery by Metchnikoff and

Roux of the prophylaxis of syphilitic contagion by calomel ointment, together with a full account of the deliberate inoculation of Dr. Maisonneuve last year, is admirably set forth in this little book. The extreme importance of the subject, from every point

of view, cannot be too strongly emphasized.

Rose and Carless.—Manual of Surgery. For Students and Practitioners. By William Rose, M. B., B. S., Lond., F. R. C. S., Professor of Clinical Surgery in King's College, London, and Senior Surgeon to King's College Hospital, etc., and Aldert Carless, M. S., Lond., F. R. C. S., Surgeon to King's College Hospital, and Teacher of Operative Surgery in King's College. and Teacher of Operative Surgery in King's College, London, etc. Seventh Revised Edition. Profusely Illustrated by 30 Full Page Plates and 554 Engravings in the Text. 8vo; 1392 pages. Price, cloth, \$5.50; sheep, \$6.50.

SAWYER.—Physical Signs of Discases of the Thorax and Abdomen. By James E. H. Sawyer, M. A., M. D.

12mo. Price, extra muslin, \$2.00.

Works on physical diagnosis are sufficiently numerous, but this one seems especially worthy, because of the concise and practical treatment of the subject. The division under methods of examination is rather original and will appeal to most readers. Distinctive diagnosis is given special consider-

ation. The illustrations are all original.

TURNER.—Aids to Osteology. (Students Aids Series.)

By Philip Turner, B. Sc., M. B., F. R. C. S. 12mo. Price, extra muslin, gilt, \$1.25.

This is another volume in the handy Students Aid

Series, which will conveniently fill the want long felt by students for a small, compact book on osteology. The descriptions are based on those of Cunningham, Gray, and Twain.

ningham, Gray, and I wain.

WALKER.—An Introduction to Dermatology. By Norman Walker. M. D., F. R. C. P. Fourth Edition. Profusely Illustrated by Numerous Engravings in the Text and by 32 Exquisite Full Page Colored Plates. 8vo; 342 pages. Price, extra muslin. \$3.00 net.

WHEELER AND JACK.—Handbook of Medicine and Therapeutics. By Alexander Wheeler, L. R. C. P. and S. E., and William R. Jack, M. D., F. F. P. S. G. Third Edition. 12mo; 525 pages. Price, muslin binding, \$2.50.

white—Common Affections of the Liver. By W. Hale White, M. D., F. R. C. P., Senior Physician to and Lecturer on Medicine at Guy's Hospital. 12mo; 310 pages. Price, muslin, \$2.00.

White on the liver is devoted to the clinical consideration of the more usual diseases of this organ. For this reason it will especially appeal to the general practitioner as a convenient reference work on this subject, while to the student it will prove of unusual value, as treating these affections in the proportion of their practical importance and frequency.

WILLIAMS.—The Natural History of Cancer. With Special Reference to Its Causation and Prevention. By W. ROGER WILLIAMS, Fellow of the Royal College of Sur-Illustrated. Large 8vo; 533 pages. geons.

muslin, \$5.00.

This book cannot fail to prove of the greatest interest to medical men. The author is well known the world over as a painstaking, conservative investigator, and whatever he writes may fairly be considered authoritative. He has devised and applied a new method of cancer research—which may be called synthetic-whereby it is shown there are modes of life, various habits, and so forth, which tend to prevent the incidence of cancer almost entirely in healthy stocks, and greatly to reduce its ravages, even among those hereditarily predisposed. The book should unquestionably be read by every one who has to treat this disease, whether physician or surgeon. The large, handsome pages, in clear type, especially appeal to the eye.

type, especially appeal to the eye.

Wolff-Einner.—The Ophthalmic and Cutaneous Diagnosis of Tuberculosis. Together with a Discussion of the Clinical Methods for the Early Diagnosis of Pulmonary Tuberculosis. By Dr. Alfred. Wolff-Einner. A Preface by Prof. H. Senator and an Introductory Note to the English Reader by C. Theodore Williams, M. D. Translated from the German by Bernard I, Robert. Illustrated by Numerous Diagrams and Large Folding Charts and 2 Chromolithographic Plates. 8vo. Price, extra muslin, \$2.75.

A full discussion of this interesting new topic, by

A full discussion of this interesting new topic, by the discoverer of the method of treatment himself.

The work is complete and thorough,

The work is complete and thorough.

Ziegler.—General Pathology, or the Science of the Causes,
Nature, and Course of the Processes of Disease. By
Dr. Ernst Ziegler, Professor of Pathological Anatomy and of General Pathology in the University of
Freiburg im Breisgau. Eleventh Edition. Translated
and Edited by Aldred Scort Warfuh, Ph. D., M. D.,
Professor of Pathology and Director of the Pathological Laboratory in the University of Michigan, Ann
Arbor, Mich. Profusely Illustrated by 604 Engravings, many in numerous beautiful Tints and Colors.

8vo; 801 pages. Price, muslin, \$5,50; leather. \$6,50. 8vo; 801 pages. Price, muslin, \$5.50; leather, \$6.50.

The Serum Treatment of Epidemic Cerebrospinal
Meningitis, with a Report of Twenty-two Cases,
By Frank Taylor Fullon.

3. The Serum Treatment of Epidemic Cerebrospinal Meningitis.—Fulton reports twentytwo cases, fifteen recoveries and seven deaths. In figuring the mortality of the entire series, if we eliminate the chronic and moribund cases, the recoveries would be 83.33 per cent., with 16.66 per cent. of deaths. The total mortality, including the chronic and moribund cases, is a fraction over thirty-one per cent. The diagnosis in this series of cases has been confirmed in every instance by a bacteriological examination. Cultures were made from the fluid obtained at the first lumbar puncture in twenty of the twenty-two cases. In one case no culture was made, but intracellular diplococci characteristic in morphology and staining properties were found in the stained smear. Of the twentyone cases in which cultures were made, a positive growth was obtained upon blood serum in eighteen, while in the remaining three the diplococcus was found in the smear, but failed to grow in culture. Smears were made always from the sediment of the fluid obtained at the lumbar puncture. In twenty cases the diplococcus was present in sufficient numbers to be found in the smear; in two cases they were not observed. In these two latter instances, however, they did grow in culture, the failure to observe them being, of course, due to the fact that not sufficient time was employed searching for them. Here might be mentioned an observation made in one of the later cases which may explain partly the failure to observe the diplococci in smears. In one instance a smear stained by Gram's method showed a very few characteristic intracellular and extracellular diplococci. This same sediment stained by Hastings's blood stain showed much more numerous diplococci both within and without the cells, and it may be that, at times in the decolorization by Gram's method, even when the Bismarck brown counterstain is used, some of the organisms are not sufficiently stained to be recog-

By WALTER G. BOWERS.

- 1. Standardization of Thyreoid Preparations. -Hunt and Seidell remark that one of the most valuable drugs recently admitted into the United States Pharmacopæia is thyreoid. The introduction of this preparation into medicine represents one of the most distinct advances in therapeutics in recent years. There is, however, a widespread belief that the various commercial preparations of thyreoid vary considerably in strength. At present there is no generally recognized method of determining their strength, save by the very tedious and time consuming one of testing them clinically. The active constituent is not sufficiently well known to admit of chemical assay, and there is no physiological test sufficiently simple and direct to admit of practical use for this purpose. At present the physician is compelled to determine the value of a thyreoid preparation directly on the patient, and thus risk giving too little or too much. Not only is time often lost by these trials, but the tests have to be repeated whenever a new preparation is used.
- 2. Miotics versus Iridectomy in the Treatment of Simple Chronic Glaucoma.-Posey states that miotics should be relied on as the sole means of treatment only in those cases which are free from attacks of so called "glaucomatous congestion," the presence of such congestive symptoms being, in his opinion, the chief indication for iridectomy; and, second, that to gain the full benefit of miotics it is necessary that they should be administered properly. Beginning in doses small enough to avoid creating spasm of the ciliary muscle, and rapidly increasing the dose until the pupil of the affected eye is strongly contracted, this degree of contraction should be maintained as long as life lasts by gradually increasing the strength of the solution, from time to time, and by instillations of the drug at intervals of every three or four hours. Conjunctival irritation may be avoided by employing only fresh and sterile solutions of the drug. Suitable cleansing washes should be administered, and attention given to the general health and especially to the condition of the bloodvessels. Careful and repeated correction of the refraction error should be made and restrictions enjoined on the use of the eyes.
- 8. Children of the Tuberculous.-Sachs observes that incidence or infection of children by tuberculous parents must, of necessity, vary with the different conditions of life. Lack of hygiene, combined with enforced closeness of contact in the homes of the poor, facilitate the more widespread dissemination of the infecting agent. While the detection of the well developed forms of tuberculosis in children is possible with the aid of the present diagnostic methods, the implantation of the tubercle germ does, no doubt, occur in a wider circle

of instances. To what extent hereditary predisposition is responsible for the development of the disease in individual cases can never be determined until the factor of infection is completely eliminated. The question of connection between tubercle infection in infancy and childhood and the manifestations of the disease in later life is still awaiting a so-The researches of von Behring, Calmette, and others are gradually turning the trend of modern medical thought toward an interpretation of the term "predisposition" as a susceptibility of the tissues dependent on antecedent infection. Of the large number of children infected through close contact with tuberculous parents, only a certain proportion present the well known manifestations of a fully developed disease of the lungs or other organs; in the vast majority the incidence of infection remains unrecognized. The increase in the frequency of tuberculosis with the advance of age from childhood to adult life makes it evident that eradication of tuberculosis in the human race can never be accomplished unless the child, first of all, is protected from infection.

9. Heart Disease.—Brown finds, naturally, many problems in heart disease. Cardiopaths may be divided into three general classes: I, Those in whom the compensation is perfect; 2, those in whom compensation is waning; and, 3, those in whom compensation is lost. The first and most fundamental step to be taken in trying to protect the cardiopath from an untimely end is publicity. Candor, attended by patient and careful explanation, will do much to assist in the correction of this widespread disease problem. Then, too, the profession should be quick to appreciate the importance of this disease problem and begin to preach with that same laudable freedom of its dangers as is now being done in the case of other medical problems. Those cardiopaths in whom the compensation is good, in whom the conductivity of the auriculoventricular bundle is good, in whom the musculature is supporting cardiac action, may need little or no medicine, but they should, nevertheless, receive the attention and direction of the medical expert as to matters affecting the lesion. The regulation of the kind and amount of exercise, the selection of vocations best suited to the support of the myocardium; the suggestion as to the curbing of certain harmful practices, the education of the cardiopath in matters of marriage, the instruction of the kind of clothing to be worn under certain conditions, the taking of baths, the character of the food, the danger of intercurrent sickness, the use of drugs, the changes of climate, and the dangers of sudden and unexpected death are some of the questions which the medical attendant should consider in treating the cardiopath in this stage. The conditions of the second and third group must be met with the same candor, but a little more skilfully and carefully. The supervision of the patients of the second group must be more constant, and the management of these cases must be more rigid. Most careful physical examinations and careful testing of the properties of the heart by instruments of precision must be conducted frequently, and remedial measures, whether medicinal or otherwise, must be instituted to regain the compensation beginning to be lost. In these cases cooperation of the patient is of the most

imperative significance, as is also the intelligent comprehension of the danger of his condition. The third group in this problem presents a syndrome only to be compared to the last stages of cancer or phthisis. But, unlike these conditions, heart disease, with its discomforting symptoms of dropsy, dyspnœa, surging heart beat and throbbing jugular, etc., offers a field for most brilliant medical achievement. So frequent are the recoveries, and so accustomed are we to these demonstrations of medical success, that proper and just credit is not accorded the physician for such efficient work, placing, as he does, a patient in imminent danger of dissolution, as surely as if he were affected by any other deadly process, in a condition of usefulness and comfort to live out the allotted life period.

10. Neisser's Vaccine in Gonorrhœal Affections.—Aronstam summarizes the results obtained by the gonococcus vaccine as follows: acute cases the vaccine acts beneficially, and the time necessary to cure the disease does not exceed four weeks. In some of the complications of gonococcic urethritis, such as epididymitis, cowperitis, and acute prostatitis, as well as in gonorrhœal adenitis and in involvement of the lymph channels on the dorsum of the penis and in posthitis of the same origin, threatening phimosis, it may be confidently relied on. No other treatment, whether systemic or local, is necessary, and irrigations and injections may be entirely dispensed with. chronic cases it is inert and acts indifferently, owing to the fact that in these conditions one has to deal with a mixed process. The conjoined use of other v-ccines, therefore, suggests itself. In these instances the gonococcus vaccine per se has reached its limitations. It is a valuable diagnostic agent. It brings to view latent or dormant conditions and thus affords a most important diagnostic means in definitely deciding on whether a given case has been actually cured, which is of inestimable value for sociologic reasons. In dormant gonococcic arthritis it will bring about a recrudescence of the disease. In this sequela it materially shortens its duration and brings about a speedy restitution to the normal. No exact rule can be laid down as regards the dosage and the intervals of the administration of the vaccines; each case must be treated individually. The future possibilities of gonococcic vaccine in particular and opsonotherapy in general are unlimited, promising to give us a new and unexplored field of scientific inquiry.

MEDICAL RECORD.

I. Thoracic Periosteædema of Angeioneurotic Origin,

2. Some Features of the Present Crusade Against Tuber-culosis in New York City,

3. Eupyrexia By CAMILO CALLEJA. 4. Early Medical Schools and Legal Regulation,

By JAMES J. WALSH.

5. Interpretation of Blood Examinations,

By IRA S. WILE, M. S. 6. A Contribution to the Subject of Syphilitic Prophylaxis by the Use of Calomel Ointment; Report of a Case, By A. L. WOLBARST.

Thoracic Periosteædema of Angeioneurotic Origin .- Stern remarks that thoracic periosteædema of angeioneurotic origin occurs much more frequently than is generally supposed; it is closely related to the acute circumscribed superficial œdema, with which it may be associated. It may be the external manifestation of periosteal swellings on the inner side of the thorax, or it may be the visible evidence of possible angeioneurotic cedemas of the mucosa of the respiratory tract disturbing the intrathoracic equilibrium. If rightly interpreted, it will always prove of diagnostic aid. The phenomenon, which is of a fleeting nature, but tends to recurrence, appears oftener in women than in men, and seems to stand in some connection with the catamenia. A prognosis as to the period of its ultimate disappearance cannot be made, but the outlook concerning its gradual diminution and that of its concomitants is very encouraging. The phenomenon requires no treatment in the majority of instances; remedial measures, however, when indi-cated, invariably call forth temporary and, occasionally, also more lasting amelioration of the sub-

jective and objective symptoms.

3. Eupyrexia.—Calleja defines eupyrexia as the pretuberculous fever, the word meaning good fever, that is, the best of all fevers, a disease almost exclusively belonging to youth and children. There are five degrees of pretuberculous affections: Neuroses, hyperæmias, fevers, inflammations, and granulations. Moreover, there are complex pretuberculous affections in which two or more of the elemental ones, just mentioned, are united. Eupyrexia is a very important and frequent disease, especially in young people, and is manifest in different forms, but the principal may be reduced to four: (1), Pseudotypic eupyrexia, which is the most typical. Belonging to this variety are many of the cases hitherto diagnosticated as intestinal infections, without specifying the cause; also many other fevers qualified as attenuated typhoids, and a great number of catarrhs of the digestive organs considered as grippal. (2) Pseudorheumatic eupyrexia, to which belong many of the cases generally qualified as rheumatic fevers. (3) Pseudopneumonic eupyrexia, which is marked by symptoms of congestion of the respiratory organs like bronchitis, transitory pneumonia, and, when it lasts long, sometimes has the appearance of an incipient consumption. (4) Pseudopaludic eupyrexia, to which belong almost all paroxysmal fevers which are not malarial and are neither septic nor pyæmic. Our first aim in eupyrexia must be to prevent hypoxygenia, that is lack of reoxygenation in the organism, which may be either primary or secondary. Primary hypoxygenia is a general asthenia due to imperfect breathing and an insufficient intake of oxygen, so that there is an imperfect compensation of the oxygen we constantly lose. Secondary hypoxygenia may be either general or local; the former is at times caused by chronic infections like lues, or chronic intoxications like alcoholism, sometimes by primary anæmia resulting from poor alimentation; and also it may be produced by a dyscrasia, especially when the individuals are narrow chested. Local hypoxygenia may be produced by traumatism and also by an idiosyncrasy; this is generally inherited from ancestors suffering from sclerotic diseases, among which nicotinism, besides the disease before mentioned, is one of the most important. In secondary hypoxygenia, the want of oxygen in the system is

the result of the tissues having lost some of their power of reoxygenation on account of their presclerotic state. Complex hypoxygenia is that in which the primary and secondary forms are combined in the same subject. Sufferers from chronic hypoxygenia are predisposed to pretuberculous affections, one of which is eupyrexia; but germs are indispensable to the development of tuberculosis. once this is produced, eupyrexia is its best natural or spontaneous curative process. Hence we must help the development of eupyrexia in those suffering from hypoxygenia, for which pure air is the best recourse. Whether he breathes or does not breathe sufficient pure air may determine whether the individual suffers from eupyrexia or from consumption. Consequently, in addition to the direct preventive influence of atmospheric air, recognized by all as a means against tuberculosis, we must not follow the old saying, "starve a fever"; on the contrary, when the first week of the fever has passed, during which it will be well to restrict the diet somewhat, we must give as much and as nutritious food as the patient can digest, so that the calories, which the fever consumes, may be made up. But it often happens that the digestive organs cannot do as much work as is necessary; then we must prescribe some preparations to help the metabolism, so that the bacilli become less virulent and the sufferer may resist the disease. For this purpose we may prescribe the phenol derivates, the arsenicals, one of the colloidal forms of silver, and organic preparations such as tuberculin, always taking care to use them in small doses, as in eupyrexia they merely produce a stimulating effect upon the cells.

By A. R. TWEEDIE,

1. Malignant Endocarditis. — Taylor states that it must be borne in mind that malignant endocarditis is a form of pyrexial complaint which may be easily confounded with typhoid fever, tuberculosis, pneumonia, or other severe infection; that it has no one definite course or duration; that, as a rule, it is characterized by a valvular lesion, by pyrexia, by other signs of general infection, and by the evidences of vascular obstruction or embolism; that in different cases pyrexia may be absent or murmurs may be absent, or there may be no evidence of vascular obstruction; that while some cases resemble typhoid fever, others pyæmia, while in others pyrexia is grafted on marked cardiac symptoms, in others cerebral symptoms are prominent; there are cases which can come under neither of these groups, and others which may be included in two or three.

2. Bees' Stings and Rheumatism.-Walker has investigated the popular belief that the poison of bees is protective against rheumatism and may also be employed for its cure. The material collected establishes nothing beyond the fact that the belief does exist. But it is highly suggestive, and in the light of recent observations as to the possible relationship between some of the phenomena of acute rheumatism and an abnormal production of formic acid in the body under the action of a streptococcal microorganism, it should be investigated further. Terc, a Styrian physician, has carried out the bee sting treatment for many years, and asserts to have had most excellent results. In rheumatic subjects, secondary itching and swelling does not follow the sting, and finally a condition of immunity is obtained. Couch alleges to have found formic acid a marvellous remedy in rheumatic conditions and in arthritis deformans. After a preliminary injection of cocaine, a two and one half per cent. solution of formic acid is injected under the skin in the neighborhood of the painful joints. Twelve or fifteen injections are made in one day, and are repeated every day or every other day until the pain ceases.

9. Prevention of Pleural Adhesion .- Grünbaum and Pitt suggest that if it were possible to keep the two layers of the pleura apart for some weeks after the inflammatory process subsides, adhesions would either not occur, or if they were formed, they would not be so dense. The obvious method is to inject fluid into the pleural cavity. Such fluid must possess two characteristics: (1) Absence of toxicity; (2) slow absorption. Liquid paraffin answers the requirements. In five cases treated in this manner there were no untoward symptoms, and the movements of the two sides of the chest became equal. But Litten's sign was not reestablished.

10. Blood Pressure.-Russell contends that the trained finger is still the only means of estimat-

ing blood pressure in clinical work; that in using the hæmomanometer the vessel wall becomes a disturbing factor whenever pathological conditions are dealt with, and that in the high pressures obtained from thickened arteries the arterial wall is the pre-

dominant partner.

18. Dermatomycoses. — Sabourand discusses the various dermatomycoses common to man and animals-favus, microsporous, and trichophytous. Cutaneous epidermic ringworms are cured by tincture of iodine diluted with five times its volume of alcohol, Ringworms of the hairs originating from animals are less tenacious and more inflammatory than the ordinary ringworms. When they evolve in the type of Kerion the treatment must moderate the inflammation by emollients and attempt absolute local cleanliness (cleaning, epilation). When they evolve without inflammation, radiotherapy well managed becomes the method of election, as in the common ringworms of the child.

19. Maxillary Sinus Suppuration.—Thomson states that in cases of suppuration of the maxillary sinus treated by lavage, the age of the patient does not influence the result. Lavage is to be preferred in patients of advanced years. The existence of nasal polypi does not make the radical operation imperative—simple irrigation may cure such cases. In long standing cases due to the pneumococcus or staphylococus lavage should be employed. But when due to the streptococcus the radical operation should be advised. When lavage is adopted, an intranasal operation should be preferred to the alveolar route. The only satisfactory method for the radical operation is through a large opening in the wall of the canine fossa.

Division of Auditory Nerve for Tinnitus. -Ballance reports the case of a woman, aged forty-nine years, upon whom he performed division of the auditory nerve for painful tinnitus, with entire success. This operation is a means of relieving a patient from distressing tinnitus and vertigo not amenable to other measures. Such patients are almost invariably deaf on the affected side, so that no sacrifice is made by cutting off the labyrinth from its connection with the brain. The operation being undertaken for disease of the labvrinth or its ganglia does not give rise to that group of symptoms which follows division of the auditory nerve or extirpation of the labyrinth in animals. moval of the semicircular canals cannot be expected to relieve a painful tinnitus. Either the cochlear ganglion must be destroyed or the cochlear division of the auditory nerve divided. Just as in division of the fifth nerve for epileptiform tic we may hope some day to spare the motor root which is in no way concerned in the disease, so in division of the auditory nerve we may hope to spare the nerve of Wrisberg, which is in no way concerned with auditory symptoms. Labyrinthine symptoms have their origin in the cochlear ganglion or in the vestibular ganglion or in both, but we cannot yet think of a method for separating surgically the cochlear and vestibular divisions of the auditory nerve so as to spare the one or the other, as the symptoms may in-

4. Serum Treatment of Cerebrospinal Meningitis .- Currie and Macgregor base their paper upon a series of cases of cerebrospinal meningitis observed during the recent epidemic of the disease in Glasgow; 330 cases were seen during two years, of which 105 were treated with antimeningococcic serum. In all but a few cases, each case was bacteriologically verified. Four different sera were used for treatment, with varying rates of case fatality. No opinion is given regarding the relative merits of the sera. Of the 105 patients so treated, thirty-nine recovered. The effects of the serum are considered in two ways-clinically and statistically. Clinically it was found that spontaneous improvement in the condition of patients was liable to occur during the natural course of the disease, alike in the acute group of cases with their critical recoveries, and in the chronic group with their oscillations between betterment and relapse. After serum treatment in the acute phase in certain cases, the temperature suddenly fell and the symptoms passed, but as noted above this early favorable termination was by no means uncommon in untreated cases. In the chronic cases also, the clinical appearances after serum treatment were equivocal. In some cases decrease of restlessness, headache, and general irritability occurred on the day following administration; in other cases two days later. In some cases the improvement was lasting; in others the symptoms recurred. Some cases again which had several injections of serum reacted differently with the different injections. were not prevented by serum treatment, either in the acute or chronic phases of the disease. In their influence on the phenomena of the disease, frequent injections and large injections did not differ from injections at longer intervals or in smaller quantity. On these observations the writers base their conclusion that the administration of serum in their cases was followed in individuals by no consistent modification of the natural course of the disease. Turning now to the statistical side of the question, of the 330 cases eighty-three patients recovereda case fatality of 74.8 per cent., which is slightly higher than in epidemics elsewhere. Of the 105 serum treated cases sixty-eight patients died, a fatality of 64.8 per cent. Of the 225 untreated cases 179 patients died, a fatality of 79.5 per cent. Considered with reference to the number of cases involved and also with reference to the fact that many cases admitted when moribund did not receive serum treatment, the difference between these percentages is barely significant. The mortality was highest among the patients in whom serum treatment was begun during the early days of illness.

writers ascribe this to the special virulence of the acute phase of the disease in the Glasgow epidemic. The authors' conclusions were generally negative with the following important exception: When serum treated survivors of the first ten days were compared with untreated survivors in respect of case fatality, they found that the treated patients recovered in greater number, and the difference between the respective percentages was sufficient to imply that serum treated patients who survived the first ten days of illness had a better chance of life. This suggests that the serum, while unable to arrest the disease outright, was yet able to hamper its progress, aiding in this way the natural defenses of the body. Most of the injections were given subcutaneously, and the writers admit that better results are obtained by injection into the spinal theca, after the withdrawal of spinal fluid.

5. Permanganate Disinfection. - Bonsfield states that except for popular use and upon vague and indefinite lines the permanganates have almost been dropped as disinfectants. The permanganates have many qualities which, given a reasonable disinfectant power, entitle them to consideration. Their very great power as generators of nascent oxygen, their nonpoisonous character, their cheapness, and lastly their distinctive color, are all features of value, while they alone possess the power of destroying the odor of putrescent matter, and of thus affording, in the absence of odor, a very evident, if somewhat rough and ready, criterion of the amount of disinfection which has been accomplished. Finally, they have the advantage of leaving the substance to which they have been applied, whether solid or liquid, in a condition in which it is incapable of giving rise to disease either by the bacteria contained in it or by their products.

4. A Case of Facial Paralysis, with Remarks on Surgical Treatment of this Affection,

By CHARLES GREENE CUMSTON. 3. The Choice of a General Anæsthetic.-Patrick says that the choice of a general anæsthetic is a question to which too little attention is given, and it is impossible in the widely varying conditions met with in practice to use one anæsthetic only to the exclusion of all others. Such a procedure is unscientific, and by no means devoid of danger. For induction, ethyl chloride or nitrous oxide followed by other is to be preferred, followed in turn by chloroform or a mixture of chloroform and ether if the operation is prolonged. He does not favor the use of ether by the closed method for operations occupying more than fifteen to twenty minutes. Mixtures of chloroform and ether are not used as freely as they might be, and are preferable to pure chloroform in very many cases, especially in the hands of the inexperienced. In dental and rectal cases chloroform is in the very large proportion of cases

SECTION II.

Specific Therapy of Pulmonary Tuberculosis. Part I, Tuberculin and Its Derivatives.

The Treatment of Tuberculosis by Tuberculins, and More Especially by Béraneck's Tuber-culin.—Dr. E. Béraneck, of Neuchatel, said that the results of attempts at antituberculous immunization up to the present time had been relative only. The results, however, were sufficient to enable one to affirm that homotypical or heterotypical tubercle bacilli were capable of conferring marked resistance upon inoculated animals. The biochemical characters of the tubercle bacillus were such that, although it might act as a "vaccine," it could not be used in its natural state in the treatment of human beings suffering from tuberculosis. Therefore it was necessary to make use of the extracellular toxines or of the intracellular toxines for the purpose of human therapy. The immunizing properties of the toxines of the tubercle bacillus justified, in the opinion of the writer, the utilization of these toxines as a specific treatment of tuberculosis.

Filtered Broth of the Bacillus of Human Tuberculosis as a Curative Agent in Tuberculous Affections of Man .- Dr. G. DENYS, of Louvain, said that since 1896 he had used a product obtained by filtering a culture of human tubercle bacilli grown upon peptonized and glycerinated bouillon through a porcelain filter. This product was used without modification by physical or chemical agents. It was equivalent to diphtheria and tetanus toxines. When a suitable dose was given, it produced inflammatory phenomena at the site of the injection, rise of temperature, nervousness, malaise, weakness, loss of appetite, and a return of the general symptoms of the disease or the appearance of new symptoms. Marked reactions were obtained with less than 0.001 milligramme. The author was convinced of the possibility of curing human tuberculosis by a complete immunization with this filtered broth, which he termed "F. B." He also maintained that he could succeed in giving as large doses as one cubic centimetre without appreciably injuring the patient's health. In the use of "F. B." all reactions were avoided except the lightest ones. Even the lighter reactions too frequently produced were considered harmful and dangerous. He began with a very small dose; 0.0005 to 0.0001 milligramme for an apyretic tuberculous patient, and 0.0000005 to 0.000001 milligramme for a slightly feverish patient. He never injected during a reaction or when a reaction was just ending; he allowed an interval of from one to several days between the end of one reaction and the next injection. He never increased the dose when there had been the least reaction. If the reaction was strong, he reduced the next dose. In general, the adaptability of individuals to the injections and the improvement of the disease in them went on hand in hand. As a result of twelve years' experience, he alleged almost certain cure in cases of "closed pulmonary tuberculosis." In apyretic, ulcerated pulmonary tuberculosis the infection was generally arrested, and the less advanced the lesions the more complete would be the cure. Patients who had had fever for a long time were less likely to be benefited, on account of the extent of the lesions. During the hectic period the chances of recovery were small. In pleuritis, laryngitis, enteritis, peritonitis, adenitis, osteitis, arthritis, and cystitis a large proportion of cases were cured. The treatment with this filtered broth did not exclude treatment by other methods. If the rules above mentioned were followed out, the treatment was absolutely inoffensive.

Antibacterial or Antitoxic Immunization in Tuberculin Treatment.—Dr. Edward L. Trudeau, of Saranac Lake, N. Y., said that there were two theories concerning the action of the biological products which were being used in the treatment of tuberculosis—one, the "vaccination" theory, which sought to produce immunity by the injection of the bacilli; and the other, toxine immunization, which attempted, by giving increasing doses of the toxine, to produce the greatest degree of toleration of the chemical poison of the bacillus. Neither method was quite satisfactory, owing to our imperfect knowledge of the mechanism of the immunizing process. At the present writing the reader preferred to adhere to the conception of an immunity that was principally antitoxic as produced by the treatment, and he considered tuberculin habituation its essential feature and the best guide to the dose. If toxine immunization was accepted as the essential feature of treatment and the guide to the dose, instead of measuring the degree of a questionable antibacterial immunity by the opsonic index or attempting to produce it more or less empirically by a series of reactions, the severity of which we could in no way control, the main features in our treatment would be: First, to raise the tolerance of tuberculin to the highest point attainable in each case by an almost imperceptible and long continued progression in doses. Second, to avoid general and local reactions as much as possible and to consider them merely as evidences of intolerance. Third, to follow no arbitrary rule as to rate of increase or maximum dose to be reached; but to be guided merely by the degree of toxine tolerance of each patient as shown by the symptoms and the general conditions, whether the highest individual maximum dose attainable was only a small fraction of a milligramme or a cubic centimetre or more.

PART II, SERUM TREATMENT.

The Maragliano Serum Treatment at the Henry Phipps Institute.—Dr. LAWRENCE F. FLICK, of Philadelphia, said that twenty members of the staff of the Phipps Institute had used the Maragliano serum and had reported upon the results obtained. Their consensus was that the serum had no specific value. The cows that had been used for making the serum were tested for tuberculosis and were found to be free from the disease. They were guarded against infection and were immunized by injections with material recommended by Maragliano. The serum given by them seemed to be as

satisfactory as the imported serum. One of these cows died of general tuberculosis, and the other cow, when she was killed, was found to be slightly tuberculous. These occurrences raised the following questions: "Can an animal give an immunizing serum and itself not be immune? Does the withdrawal of serum from an animal deprive it of its protection against the tubercle bacillus?"

The Untoward Effects Following the Use of Maragliano's Serum.—Dr. H. R. M. LANDIS, of Philadelphia, said that, of forty-one cases of tuberculosis treated with Maragliano's serum, seven, or seventeen per cent., showed evidences of marked supersusceptibility, such as suffused face, dyspnæa, cardiac oppression, rapid pulse, lumbar pain, muscular tremors, and a sense of impending death. The were no fatalities. There seemed to be no definite time for the occurrence of these phenomena of anaphylaxis; the symptoms had developed after the third to the twenty-second injection. The doses had been from one to three cubic centimetres of the serum. The patients who were treated with this serum were all with advanced or moderately advanced cases, and were confined to bed. Ambulant cases did not show anaphylaxis; four of six ambulant patients had the "serum disease." Skin eruptions were seen in six cases. The other phenomena were herpes labialis in one case, herpetic eruption about the site of the injection in three cases, severe inflammatory reaction at the site of the injection in seven, enlarged and tender lymph nodes in ten, severe joint pains in three, and severe lumbar pain

SANATORIA, HOSPITALS, DISPENSARIES, AND HOME TREATMENT FOR THE TUBERCULOUS.

The Value of Sanatorium Treatment. -ARTHUR LATHAM, of London, said that sanatoria were essential to the successful treatment of pulmonary tuberculosis on a large scale, and that they were essential to any scheme directed toward the eradication of the disease, provided they were used intelligently. The majority of sanatoria, however, were inefficient. The following objections might be advanced against sanatorium treatment: Sanatoria were regarded by some physicians as sufficient in themselves for the management of cases of tuberculosis and as certain to effect a cure in nearly every The erection of sanatoria cost too much money. It was held by many that it would be impossible to provide the necessary funds to pay for the treatment of the majority of sufferers. When the head of a family was at a sanatorium it was very difficult to make arrangements to support the dependent members of that family. It was, furthermore, difficult to find work for the head of the family on his return from the sanatorium. On the other hand, the value of sanatorium methods was increased by the use of tuberculin. The treatment in a sanatorium was of great value from the point of view of education. The value of the treatment was much increased by the knowledge obtained from the observation of the patients treated in them, concerning autoinoculation and the response of the recuperative forces to the action of tuberculin.

Graduated Labor in Pulmonary Tuberculosis.

—Dr. M. S. PATERSON, of Frimley Sanatorium.

England, said that it was erroneous to believe that

work was to be employed in the treatment of every case of pulmonary tuberculosis and at all times. The system of graduated labor at the sanatorium of which the reader had charge began with extreme rest. It had been shown that the opsonic index was modified by exercise in cases of pulmonary tuberculosis, as well as that the temperature was influenced by it. This influence upon the opsonic index and the temperature was considered to be due to the toxines produced at the seat of the lesion, autoinoculation, in other words. In the Frimley Sanatorium patients with a temperature of 99° F. and over, and headache, were sent to bed, and were not allowed to wash themselves or to go to the lavatory. Every possible means was adopted to prevent nonproductive coughing attacks. The graduated exercises were begun after the temperature had reached normal, a constant watch being kept upon the curve. amount of work done was gradually increased under constant supervision until such time as they could perform the heaviest work without a rise of temperature. The symptoms indicating autoinoculation were loss of appetite, the performance of the work as though it required considerable effort, an irregular swinging temperature, usually below normal, a temperature of 99° F., with headache.

The Effect of Exercise on the Opsonic Index

of Patients Suffering from Pulmonary Tuberculosis.—Dr. A. C. Inman, of Brompton, London, said that autoinoculation occurred spontaneously in the febrile stage of pulmonary tuberculosis. In a less active stage these autoinoculations did not occur spontaneously, but they were produced by exercise or movement sufficient to affect the focus of the disease. Autoinoculation was manifested by a variation in the opsonic index. Such a variation did not occur in nontuberculous subjects. When graduated exercises or graduated labor methods were being used in the treatment of pulmonary tuberculosis, tuberculin elaborated from the patient was being used in the treatment of the condition. Of the patients investigated at the Brompton Hospital, ninety-five per cent. had a high opsonic index at some time during the day. These patients, however, were all doing appropriate work and had normal temperatures. A rise in the temperature corresponded with a negative opsonic phase, and indicated an excessive autoinoculation, which required rest in bed for its cessation. When active exercise was followed by no variation in the opsonic index, when a variation had resulted on former occasions, the presumption was that the disease was arrested. He was of the opinion that patients might be classed as having had the disease arrested even though there were still tuberele bacilli in the sputum.

The Application of Rest and Exercise in the Treatment of Tuberculosis.—Dr. F. M. POTTENGER, of Monrovia, California, said that the functions of the body were best carried on when the alternation of rest and exercise could be prescribed in suitable proportions. The amount of each of these factors must be determined by the natural resisting power of the patient and the extent of the disease present in him. In prescribing rest and exercise the conditions of the respiratory, circulatory, digestive, and muscular systems must all be considered, and special attention must be directed to the condition of the heart and the ability of the patient to exercise

without causing fatigue, increase of cough, dyspnœa, or rise of temperature. Exercise was the cause of autoinoculation, on account of the passage of toxines from the diseased area into the blood stream. The symptoms resulting were practically the same as those following an injection of tuberculin. In such conditions, however, the dose of tuberculin could not be controlled; the patient received the dose at a time when he was tired, and when he was not able to respond to his fullest capacity with the production of antibodies. Such a method of autoinoculation could not be considered a scientific method of administering bacterial "vaccines" or toxines. If work was to take the place of carefully prescribed exercises in treating charity patients, the work must be prescribed according to the needs of the individual, and not according to a routine list made out for another No patient should be allowed to do work which was not consistent with his powers of endurance. No patient should ever have a task assigned to him which he could not leave at the moment it began to tax his strength.

(To be continued.)

Book Aotices.

(We publish full lists of books received, but we acknowledge no obligation to review them all. Nevertheless, so far as space permits, we review those in which we think our readers are likely to be interested.)

A Manual of Fever Nursing. By REYNOLD WEBB WILLOX, M. A., M. D., LL. D., Professor of Medicine at the New York Postgraduate Medical School and Hospital, etc. Second Edition, Revised, Illustrated. Philadelphia: P. Blakiston's Sons & Co., 1908. Pp. 229. (Price, \$1.)

Professor Wilcox has collected his lectures on fever nursing which he delivered to the nurses of St. Mark's Hospital, of New York, during the season of 1907 and 1908. The subject has been very completely and comprehensively treated, in accordance with the present state of practice, and the thirteen illustrations, mostly specimens of temperature charts in different diseases, have been well selected.

The book is indeed a manual, as it does not necessitate any preliminary knowledge on the subject, but begins with the definition of fever, its causes, physiology, varieties, etc.; demonstrates the thermometer and how to use it; treats of the pulse and respiration; speaks of the treatment, diet, and disinfection; and leads up to the continued and intermittent fevers, the fever in exanthemata, and thermic fever. It is certainly a very good compendium on the subject.

The Ready Reference Handbook of Diseases of the Skin.

By George Thomas Jackson, M. D., Professor of Dermatology, College of Physicians and Surgeons, New York, etc. With 99 Illustrations and 4 Plates. Sixth Edition, Thoroughly Revised. New York and Philadelphia: Lea & Febager, 1668. Pp. 17 to 737.

Dr. Jackson's excellent handbook has been conscientiously revised, and new articles have been added on black tongue, dermatitis verrucosa, keratosis follicularis contagiosa, keratosis senilis, lichen obtusus, melung, pseudo-pelade, and sporotrichosis hypodermica. Several of the illustrations also are

The book, thus well brought up to date, will doubtless hold its own for a long time to come as a very convenient and trustworthy manual.

BOOKS, PAMPHLETS, ETC., RECEIVED.

Report on the Prevention of Malaria in Mauritius. By Ronald Ross, D. P. H., F. R. C. S., D. Sc., LL. D., F. R. S., C. B., Nobel Laureate, Président honoraire de la Société médicale de l'Île Maurice, etc. London: Waterlow & Sons, Limited, 1908. Pp. ix-202.

A Textbook of Operative Surgery. Covering the Surgical Anatomy and Operative Technic involved in the Operations of General Surgery. Designed for Practitioners and Students. Army Intelligence:

Official list of changes in the stations and duties of officers of the Medical Corps of the United States Army for the week ending October 23, 1908:

Promoted from ASHBURN, P. M., Major, Medical Corps. captain, with rank from June 24, 1908.

BETTS, C. A., Medical Reserve Corps. Ordered to active duty at Fort Lawton, Wash.

BLANCHARD, R. M., Captain, Medical Corps. Relieved from duty at Fort Wingate, N. M., and ordered to Fort Sheridan, Ill., for duty.

BUCHSBAUM, MAURICE, First Lieutenant, Medical Reserve Corps. Ordered to active duty at Fort D. A. Russell, Wyo.

CHURCH, J. R., Major, Medical Corps. Promoted from captain, with rank from May 1, 1908.

Cole, C. Le Roy, Captain, Medical Corps. Promoted from first lieutenant, with rank from May 13, 1908.

FIFE, J. D., Captain, Medical Corps. Relieved from duty at Fort Slocum, N. Y., and ordered to sail from San Francisco, Cal., November 5, for Philippine service.

FORD, J. H., Major, Medical Corps. Promoted from captain, with rank from May 20, 1908.

HENNING, O. F., First Lieutenant, Medical Reserve Corps. Granted leave of absence for ten days, to take effect about November 20th; relieved from active duty at the expiration of leave.

LEMMON, ROBERT, First Lieutenant, Medical Reserve Corps. Granted leave of absence for one month.

PARGON, J. A., First Lieutenant, Medical Reserve Corps Ordered to active duty at Fort Yellowstone, Wyo.

QUINTON, W. W., Captain, Medical Corps. Arrived in New York on sick leave of absence for one month.

Presonn, F. P., Major, Medical Corps In addition to present duties, will take charge of office of chief surcoon, Department of Dillota, during the absence of Colonel George W. Adair.

STEPHENSON, A. V., First Lieutenant, Medical Reserve Corps. Arrived in San Francisco, Cal., on the Sheridan for treatment at the Army General Hospital.

REFLEX NEUROSES ARISING FROM OCULAR AND NASAL ABNORMITIES.*

> By S. Lewis Ziegler, A. M., M. D., Philadelphia.

Attending Surgeon, Wills Eye Hospital; Ophthalmic Surgeon, St. Joseph's Hospital.

Reflex neuroses are not the property of the savage, but of civilized man. The more refined we become in the crucible of civilization, the more must we pay the penalty of that civilization through the neurotic tendencies which we either inherit or acquire. This underlying neuropathic predisposition is unfortunately present in a large proportion of the American population, and, when not inherited, is due chiefly to the irritating action of our changeable climate, some of the effects of which have been shown by Mitchell1 and Lewis2 in their study of chorea. To this and to the ambition to equal or surpass the activities of our rivals and associates may be ascribed our highstrung nervous energy, and inordinate desire to "hustle." If sooner or later there comes a nervous breakdown we may add this complication to our predisposing cause. On the other hand, the search for the locum tenens of the exciting cause has often proved to be as elusive as "the search for the glittering pearl.'

Reflex nervous disturbances have long been ascribed to perverted nerve impulses originating in peripheral end organs. Dental irritation from delayed eruptive teeth in children, phimosis, or adherent prepuce, incarceration of a nerve filament in the cicatricial plug of a uterine laceration, or an uncorrected depressed fracture of the skull, have all contributed their quota to the causation of minor epilepsy, habit chorea, vertigo, localized muscular spasms, neuralgia, neurasthenia, and gastric neu-

INFLUENCE OF THE EYE ON REFLEX NEUROSES.

That the eye is a most prominent ætiological factor in these systemic reflexes has long been conceded by careful observers. Ever since Donders, in 1864, called the attention of the medical world to the fact that the group of symptoms known as asthenopia could be relieved by the proper refraction of the eye

and the careful adjustment of glasses, our knowledge of the deleterious effects of eyestrain on the human organism has been steadily growing.

In those earlier days, when refraction was passing through its formative stages, the work of such Philadelphians as Dyer, McClure, Thomson, Norris, and Harlan in the diagnosis and correction of astigmatism was of inestimable value in the development of what we today term "modern methods of refraction." While these were the writers and lecturers of their day, there were other pioneers such as Goodman, Levis, and Morton, who gave great impetus to the work of practical refraction and won a large clientèle by their successful methods. It was not, however, until Weir Mitchell' accepted these results at their true face value, and publicly endorsed them, that the medical profession at large became properly impressed with these new truths in ophthalmology. From that day until this, a period of almost three decades, the subject of ocular reflexes has been a controversial one, those most interested ranging themselves either as enthusiastic endorsers or as uncompromising unbelievers, while the conservative middle ground was but sparsely occupied.

Curiously enough, those who have been termed the "muscle faddists" early began to make a most active crusade in favor of eyestrain as the chief cause of many reflex neuroses, later on, however, advancing the statement that muscular imbalance was the real source of these pathogenic impulses. As far back as 1876, Stevens' was impressed with the relation of evestrain to systemic neuroses, which he at first relieved by refraction alone. Gradually his attention was shifted from this and centred upon muscular imbalance6 as one of the chief causes of these disturbances, which he then corrected by the adjustment of prisms. A decade later he became obsessed by the idea that all reflex neuroses should be ascribed to muscular errors, which could only be properly corrected by partial tenotomies of the opposing muscles. While his views as a whole have been endorsed by few, many have accepted them in part, and all have given him credit for a valuable nomenclature of muscular terms, a new and practical operation for the relief of heterophoria, and much original investigation of this intricate subject.

Ranney', who was a neurologist with a penchant for the practice of ophthalmology, accepted these views in their entirety, and, while he also acknowl-

edged the necessity for the most careful preliminary refraction, which often gave the desired relief, he proceeded to examine all cases of reflex neuroses for muscular imbalance, and to perform tenotomies for their relief. He stated that he had cured many cases of epilepsy, chorea, and weak mentality. So careful an observer as the late Dr. Noyes10, who was then one of our leading ophthalmologists, placed himself on record as being conversant with many of Ranney's successful cases, and in part endorsed his views.

Following this came a veritable cyclone of heterophoric studies on the use of prisms, muscular gymnastics, and partial tenotomies for the correction of muscular errors and the relief of these complicating systemic reflexes. To this "symposium" Savage contributed much original research in muscular anomalies, operative methods, and the demonstration of new theories, always conceding, however, the therapeutic value of properly corrected ametropia" in relieving headache, migraine, and other reflex disturbances.

. Gould13 tried to stem the tide of "tenotomies" by advocating a return to the older method of prism exercises, but, not succeeding, declared "surgery the despair of medicine," abandoned all ophthalmic surgery, and devoted his attention wholly to refraction. He, however, adopted the entire symptomatology of his foes, the "muscle faddists," and stated that complete relief from this host of reflex neuroses could only be obtained by properly adjusted glasses. He undoubtedly alleged too much. Nevertheless, there is much of undisputed truth in what he says, which is all the more reason for calm, dispassionate statements.

The views of de Schweinitz14, who has voiced the feeling of the profession in the matter most fairly and concisely, are of great interest in this connection because of his well known conservatism. He says:

It is unquestionably true that fully seventy-five per cent. of ocular disorders depend on anomalies of the refraction, accommodation, and motility of the eyes. Correction of such faults is followed by the greatest good to the eye and to the general organism in which the strain has been interpreted by accommendation. terpreted by symptoms not necessarily suggestive of their origin. When one comes to think about them, these symptoms stretch out into an extraordinary train, but we have ceased to wonder, and as a matter of course investigate or cause to be investigated the eye whenever searching for the ætiology of headache of all kinds, vertigo. nausea, pseudo and habit chorea, neurasthenia, and other disease phenomena of similar manifestation. We have learned that many so called gastric troubles, tachycardia, flatulent and other types of dyspepsia, indigestions, night terrors, especially as they occur in children, may have a like origin, and we have found out that pains strangely and persistently situated in the nape of the neck, between and under the shoulder blades, at the end of the spine and deep in the matter of the neck of the spine and the neck that the neck of the spine and the neck that the deep in the mastoid may owe their origin to the same cause. These facts are widely, I think I may say universally, known, although, curiously enough, many of the most important of them find no place in the most used textbooks on general medicine

these, when he says, "Who has not seen correction

of errors of refraction relieve so called 'bilious attacks,' periodical vomiting, anorexia, indigestion, and other gastric symptoms?" The cure of grave organic ocular defects relieves similar gastric con-

Hansell¹⁶ has carefully summed up this interrelation between the eye and the general system in saying: "Any theory of the origin of disordered function which does not embrace a consideration of the ocular apparatus is unscientific and open to criticism. There are incessant demands on the peripheral organs of vision which are in direct connection with the central nervous system, and the many ways in which this connection is provocative of disordered function is a fact of deep significance in the causation of disease. The cause or association is, moreover, continually active during the life of the individual.

Many distinguished neurologists, such as Wood17, Gray18, Starr18, Féré28, and Pritchard21, have endorsed these views in part, by acknowledging the ætiological entity of uncorrected refractive errors, but not conceding the equally deleterious effects of muscular imbalance; while others, whose experience has been different, still remain unconvinced that ocular

defects can excite reflex disturbances.

The unbiased observer must concede at least four ocular factors which may become the exciting cause in producing reflex neuroses: 1, Ciliary spasm, or strain from uncorrected ametropia; 2, accommodative effort, whether in youth or old age (presbyopia); 3, muscular imbalance; and, 4, painful ciliary scar, or shrunken eyeball. As has been previously pointed out, the underlying, predisposing cause must be present and active. Hence these factors are most liable to originate reflex symptoms in the neurotic subject, while the phlegmatic individual may wholly escape their deleterious action.

I. Eyestrain from uncorrected ametropia stands

at the head of the active factors causing these annoving reflexes. It takes its origin in the ciliary effort made to overcome errors in the static refraction, or to correct axial defects. These errors are hypermetropia, myopia, and astigmatism in varying combinations. As the ciliary muscle may act irregularly, spasmodically, and unequally, its action must be wholly suspended by complete cycloplegia in order that the ametropia may be accurately measured. Having carefully ascertained the total refractive error, we must make due allowance for the free play of the ciliary muscle in prescribing the correcting glass. Failure at this point may wholly annul our efforts to remove the exciting cause. Too strong a glass will blur the vision, while too weak a cor-

the happy medium. 2. Unusual accommodative strain is a fruitful source of reflex disturbances. The accommodation should, therefore, be tested in every case, and a careful record made. Subnormal accommodation may be found in the eyes of children or youths, as

rection will not relieve the strain; hence, failure from either extreme should be avoided by ordering

well as in those of adults, but it is manifested chiefly after the age of forty, when it is known as presbyopia. The eye may be quite comfortable under the distance correction and still suffer whenever near work is attempted. An additional correction for near work must, therefore, be ordered in every case of subnormal accommodation, whether young or old. Neglect of this simple measure will often result in failure to secure the desired relief.

3. Heterophoria, or imbalance of the extraocular muscles, has long been conceded to be a most vicious agent in the causation of these reflex neuroses. Errors in the vertical muscles (hyperphoria) are probably more active because harder to overcome, while the horizontal disturbances (esophoria and exophoria), although more amenable to treatment, are, nevertheless, most persistent in causing these perverted nerve impulses. We have at our command four different ways of remedying these defects: I. Correction of the error through correction of the refraction; 2, correction of the deviation by the adjustment of prisms for constant wear; 3, orthoptic training or prism exercise; and, 4, readjustment of the tendinous insertion by partial tenotomy. Some may escape these deleterious effects through monocular vision, while others with good vision in both eyes may not possess the power of binocular fusion. The physician who ignores the proper correction of muscular errors simply courts failure to relieve many systemic reflexes, by overlooking a most important exciting cause.

4. All observers agree that painful scars may cause annoying reflexes, and scars in the ciliary region are no exception to this rule. Traumatism of the ciliary body, pressure on the sharp spicules of a chorodial bone, or the undue shrinkage of an old phthisis bulbi have all demonstrated the necessity of enucleation in order to remove the exciting cause. Numerous cases of epileptiform seizure have been relieved in this way (Stevens²², Stoewer²³, Galezowski24), which simply goes to prove the contention of Landon Carter Gray that epilepsy is only a symptom, and may be either central or peripheral in origin

NASAL ORIGIN OF REFLEX NEUROSES.

Although but little attention has been given to the nasal origin of systemic reflexes, many well known observers have recorded their affirmative views. H. C. Wood has expressed the opinion that diseases and malformations of the nasal cavity, and aural lesions, may give origin to habit chorea and minor epilepsy. Pritchard coincides with these views, laying special stress on cases of obstructive disease of the nasal passages. Stoewer states that many reflexes are cured by the removal of painful scars, or irritation from the nose and ear; while Starr concedes that local spasmodic twitchings of the head and neck may possibly be caused by nasopharyngeal irritation.

That many ocular symptoms may be duplicated or caused by intranasal lesions must be accepted as a verity. There is a "deadly parallel" of reflex symptoms that will tax one's diagnostic ability to the utmost in properly locating their origin. Many such patients who pass from one oculist to another with but slight change in glasses and but little relief are what might be termed "nasal asthenopes." They will never find ocular comfort until the intranasal lesion is corrected. It is often necessary, however, by careful refraction, to eliminate the ocular element by the process of exclusion before proceeding to the nasal treatment. Nieden26, who was a pioneer in the study of the relation between diseases of the eye and nose, endorsed these views when he said: "I would add that from my own observation there are many cases of asthenopia with inability to use the eyes for any great length of time, with symptoms of dazzling, and inability to fix objects, and for which with entire absence of all pathological alterations in the eyes, or of other visible causes, we can find no other rational reason than a chronic nasal catarrh; whilst finally, all the asthenopic disturbances disappear when the nasal disease is relieved.'

What, then, are the nasal conditions that may originate these perverted nerve impulses? The three most active ætiological factors are: 1, Pressure contact; 2, hyperæsthesia; and 3, nasal obstruction.

I. The first and most important causative agent is a condition which we may term pressure contact. The middle turbinate bone is usually the offending member, and is so often wedged in between the two vascular cushions of an engorged inferior turbinate and a sensitive septal puff that many mystifying reflex impulses are originated, the most pronounced of which are localized muscular twitchings or choreiform movements of the face, head, and neck, while intense frontal headache and eyeache are more frequent effects. The middle turbinate, however, is not always the offending member. I have seen the pressure contact of a sharp sæptal spur digging into an inferior turbinate cause similar disturbances, which were promptly relieved by the removal of the spur. The pull of a contracting adhesion between the middle turbinate and the sæptum may also cause annoying reflexes.

2. Another important ætiological element is hyperæsthesia of certain areas in the upper air chambers of the nose. These sensitive points I have found to be most frequently located in a hyperæsthetic area covering the tubercle of the sæptum, which, when irritated, quickly becomes engorged by vascular dilatation, and thus makes pressure contact against the closely approximated middle turbinate. Irritation of this sensitive area is so provocative of distinctly localized eye symptoms that I have long since dubbed it "the eye spot of the nose." Supraorbital neuralgia, referred eyepain, lacrimation, burning or smarting of the lids, blepharitis, conjunctival congestion and other similar disturbances, may result from this reflex manifestation. The "therapeutic test" of this oversensitiveness may be verified by the simple act of making a local application to this area. This will frequently precipitate an attack which the patient will recognize as very similar to the condition from which he seeks relief. If this area is so sensitive to the mild touch of an applicator, what may we not expect as the result of

Unemst and Neurologist, January, 1880.

2Pepper's American Technologi, p. 620.

prolonged pressure contact? In fact, we must accept as an infallible rule the dictum that pressure contact in the nose will always excite some reflex disturbance when any hyperæsthetic area is impinged upon. If, therefore, the middle turbinate interferes, it must either be removed, or broken and set over. On the other hand, if the sensitive sæptal puff is too large or becomes too easily engorged, it must be reduced or "pinned down" by interrupted linear cauteriza-

3. The third active agent is nasal obstruction, which, as Pritchard observes, may become an important pathogenic factor. We should never forget that normal respiration occurs only through the superior meatus of the nose. Interference with free breathing necessarily produces suboxidation, which, by increasing the sensitiveness of the whole system, renders it more liable to reflex disturbances. In order, therefore, to restore nature's supreme function of unimpeded respiration, it may be found necessary either to remove the middle turbinate, to shrink the inferior turbinate by cauterization, or even to excise the tonsils, if too large; for without free breathing health cannot exist.

While it is not my purpose to unduly emphasize the nasal phase of the subject in an address on ophthalmology, I shall, nevertheless, call attention under each individual heading to the possibility of such error, and where necessary, cite illustrative cases or draw comparative inferences.

INDIVIDUAL MANIFESTATIONS OF REFLEX NEUROSES.

Headache.—Headache has been conceded by all to be the one prominent symptom of eyestrain. Occasionally it is wholly absent. It is usually frontal in character and exaggerated by use of the eyes, growing worse as the day advances, reaching its crisis in the evening, and often superinducing insomnia. There is a great variation in the tolerance of the eye to high errors of refraction, but in neurotic subjects even low grade errors may create a veritable "nerve storm." This pain frequently shifts from the supraorbital to the temporal region, and at times may become vertical. More infrequently the eyeball itself develops a feeling of soreness. Occipital headache, on the other hand, is the salient symptom of disturbances in the balance of the extraocular muscles. It may be a deeply seated, boring pain, or only a stiffness at the back of the neck. usually accompanied by carsickness (panorama headache) and light annovance (theatre headache), and can thereby be distinguished from a similar headache caused by certain intranasal lesions.

Intense frontal headache on first awakening in the morning occasionally arises from eyestrain, but is usually nasal in origin, and can sometimes be differentiated by the mere act of bending forward. If there is intranasal pressure this suddenly increased flux of blood will cause exaggeration of the pain. If the patient is awakened during the night by a sudden, stablike, frontal pain, we may consider this of nasal origin, as mouth breathing allows vascular stagnation in the nasal chambers, and the long continued pressure contact often precipitates an attack of neuralgic pain. This attack may disappear on awakening, may continue

throughout the day, or may be quiescent during the day and reach its crisis at the twilight hour. A "Sunday morning headache" is usually nasal in origin, the result of prolonged pressure contact following overindulgence in sleep. A "Monday morning headache," on the other hand, is more liable to follow the indiscretion of excessive Sunday reading, and is, therefore, ocular in origin. Another morning headache of ocular origin may be the delayed manifestation of a "theatre headache" which had its origin the night before. This usually arises from one of three causes: 1, Light annoyance, in heterophoric patients; 2, unusual strain of both superior recti, from sitting close to the stage and directing the eyes upward; and, 3, the eyestrain of ametropia.

To demonstrate the necessity of carefully examining the nose when glasses fail to give relief, I will cite an illustrative case:

Case I.—A neurasthenic young lady consulted me eight vears ago for multiple head pains. She had been refracted by several excellent oculists without relief. My test met with just as indifferent success. I then advised her that the nose was at fault, but she did not accept this advice. For the next six years she passed from one office to another, "receiving but slight changes of five degrees or over in her astigmatic axis," but still without relief. When she returned one year ago she consented to have nasal treatment. I removed the middle turbinate on the side of greatest pain, and cauterized the other side. She has been most comfortable ever since, having gained in health, strength, and mental composure, and can now wear her glasses with comfort. Here both nose and eyes were at fault, but the head pains she sought relief from were wholly nasal in origin.

Migraine.—Migraine, or sick headache, occurs in paroxysms of greater or less severity at irregular intervals, and may reach the extreme condition of what is known as "blind headache." Scotoma scintillans is a very frequent symptom, and hemianopsia is not uncommon in these neuralgic attacks. Nausea and vomiting may be concomitant disturbances. While these cases often originate in high degrees of astigmatism with asymmetric axes, the lower grade errors have been known to excite similar disturbances in neurotic subjects. In the majority of these cases, however, some error in the muscular balance will usually be found (chiefly hyperphoria), which prisms may temporarily relieve, but sooner or later demands operative interference.

Many minor neuralgias about the head and face have been relieved by the proper correction of refractive errors. It may be somewhat difficult to explain the exact method of causation of such disturbances, but it is not difficult to demonstrate their cure, when relief is so promptly gained following the adjustment of glasses. Conservative men like Risley^{2†}, Hansell²⁰, Weeks²⁰, Zentmayer³⁰, and Zimmerman³¹ have recently placed themselves on record as favoring the ocular origin of migraine in at least a portion of the cases. The refractive error is, of course, only the exciting cause. If, therefore, these reflexes should reappear, the refraction must be carefully retested and new glasses ordered to correct any physical change.

CASE II.—Male, aged fifty-four, intelligent but neurotic, was wearing glasses to correct hyperopia with presbyopia, and a one and a half degree prism for hyperphoria, but with only intermittent relief from his migraine. Here par-tial tenotomy gave the desired relief, and led the patient to remark that "where once he suffered the torments of the damned after a half hour's reading, he could now read fourteen hours with comfort."

On the other hand, we must not forget that some of these cases, even though complicated with an ocular defect, are wholly nasal in origin. The therapeutic test will prove this.

CASE III.—A young lady—also a typical case—was carefully refracted while at school by a prominent oculist, and was still wearing the same glasses with comfort. There was no relief, however, from the "nerve storms" that were ushered in by light flashes, hemianopsia, excruciating headpains, and finally almost total obscuration of vision. It was found that nasal applications would yield temporary relief. Excision of the left middle turbinate and cauterization of the right inferior turbinate have brought about almost complete immunity, there having been but one mild attack during the past year.

CASE IV.—A physician had long suffered from typical migraine. A careful refraction was made, glasses ordered, and worn. Eyes are now comfortable but migraine persists. The attacks are ameliorated by local applications to the nose. The pressure contact present in the nose is un-doubtedly responsible for his suffering, but he still hesi-

tates to undergo the slight operation necessary. Localized muscular spasms.—Muscular spasms, such as blepharospasm, facial twitchings, jerking of the head, head tilting, spinal curvature, and other like disturbances have been noted as the result of ocular defects. Head tilting may come from two causes, I, the effort to bring into alignment eyes that are displaced by faulty muscular balance, chiefly in the vertical (hyperphoria), and 2, the attempt to gain a clearer view of objects through an oblique astigmatism. Spinal curvature, on the other hand, comes more frequently from inequality in the length of the limbs, causing tilting of the pelvis and displacement of the spinal column, with its attendant backache. The addition of a high heel to the shorter limb, under the supervision of an orthopædist, will promptly relieve this, as was first demonstrated by the late Dr. Goodman, who was both an orthopædist and an oculist. While blepharospasm frequently arises from eyestrain, it may also occur from loss of sleep, mental exhaustion, and excesses in coffee and tobacco. Intranasal lesions must also be reckoned with as ætiologic entities.

CASE V .-- A young lady suffered from asthenopia, blepharospasm, and occasionally some twitching at corner of mouth. Asthenopia was relieved by refraction, but twitching persisted. Excision of a tightly pressing right middle turbinate, and cauterization of the left inferior turbinate, brought relief from the spasm, and physical comfort

through improved breathing.

Case VI.—A mechanic had been suffering from left sided facial twitching and blepharospasm, rhythmic in character, occurring every two minutes, awake or asleep, for over five years. He had no error of refraction. The left middle turbinate was pressing hard against the inferior turbinate, and in places adherent to it. The middle turbinate was carefully removed. As healing progressed the gradual lessening of the spasm could be noted, first to an interval of ten minutes, then to one hour; later he passed a comfortable night, and finally but one or two mild spasms occurred during the day. Having convalesced thus far he told me he was again able to talk without making a wry face, and had secured an excellent position. He thus disappeared from observation.

Case VII A painter had suffered for twenty years with

marked facial spasm and jerking of head to the left, at the

same time protruding his tongue in a curious manner. He was hyperopic, astigmatic, and presbyopic. Glasses re-lieved the refractive error, but spasm persisted. Examination showed that the right middle turbinate was digging into the sæptum. I broke it in its middle third and set it over. Improvement was most marked, but was not permanent because contraction occurred, again bringing the bone into pressure contact against the sæptum. The middle turbinate was then excised, following which conva-lescence was progressive up to complete recovery.

Chorea.-It has been asserted by Ranney and Stevens that a majority of choreics can be relieved by the proper adjustment of glasses or by tenotomies where muscular errors exist, but other observers do not wholly accept these views. In the first place, it is exceedingly difficult to make an accurate study of ocular defects when the head movements are such as almost to prevent a satisfactory examination, and in the second place, there are many other contributing causes, such as the atmospheric conditions in March, which Mitchell and Lewis have shown to be prominent factors.

Cheney believes that choreics often recover without treatment, but is convinced that their rapid recovery after correction of muscular or refractive errors makes it more than probable that these defects bear a causal relation. Starr and Gray believe that refractive errors may cause chorea and local muscular twitching, but do not concede the possibility of muscular anomalies causing reflex disturbances. Wood33 is, however, more decided in his views when he says: "Especially are eyestrain and nasal difficulties apt to cause in childhood persistent chorea, and it is, therefore, essential in every case which resists treatment to thoroughly examine these organs." Weir Mitchell and Osler acknowledge the causal relation of eyestrain in habit chorea. My experience has convinced me that in some cases the eyes may be the exciting cause. I will cite an example.

CASE VIII.—A youth, aged fifteen, was of a nervous temperament, ambitious, and very studious, a musical prodigy He had suffered from habit chorea for two years. He acci dentally complained of his eyes, and was referred to me for refraction. A cycloplegic test revealed hyperopia with astignatism, for which glasses were ordered. There was prompt cessation of the choreic movements. I have retested him after an interval of eight years, and find him grown to be a healthy, bright young man, without any recurrence of these attacks.

On the other hand, where the element of oxidation is such a prominent factor, it would seem as though an obstructive nasal lesion would be a pathogenic entity to be contended with, even though pressure contact was present.

CASE IX.-A French girl, neurotic but dull, had more or less mental hebetude. She was thin and anæmic, with dusky skin. Following an attack of grippe she developed chorea, the chief symptom being a jerking of the head backward. There was also some twitching of the body. By supporting the head with the hand held on the back of the supporting the lead with the had been accessed and except a meek, she could eat or converse. In right nostril there were adhesions between the inferior and middle turbinate, and the middle turbinate was jammed tightly against the sæptum. She never stooped or bent over, as her symptoms at once became exaggerated and a severe headache was precipitated. The eyes were free from refractive error. The right middle turbinate was carefully removed, and the left inferior turbinate was cauterized. She was thereby freed

 Abelies of Pachatres, Lamery, 1897.

from the nervous irritation, and increased oxidation has brought her rosy cheeks, a gain of thirty pounds in weight, and more mental nimbleness than she had ever before

Minor epilepsy.-Petit mal belongs to the same category as chorea. Its pathology is uncertain. Neurologists like Wood, Gray, Féré, and Stoewer believe that this condition may originate in eyestrain. Some cases, if not cured, have at least been benefited by treatment of the congenital ocular defects. Stevens, Ranney85, Gould30, Colburn37, Capps88, and Reber" have reported cases relieved by correction of refractive errors. On the other hand, Stevens, Stoewer, and Galezowski have each reported cases of reflex epilepsy from ciliary injury or irritation that were relieved by enucleation of the eyeball.

I have followed with great interest two patients who first consulted me about six years ago. One suffered from an error of refraction, and the other from a nasal lesion. Strangely they were both so fond of sweets that they indulged in "candy sprees." I do not recall having read that the ingestion of sweets is an exciting cause of epileptiform seizures. I presume physiological chemistry might explain this as due to the breaking up of the carbohydrates, and the liberation of an excess of carbon dioxide into the blood.

CASE X .- A young man with subnormal mentality, no occupation had a neurotic family history. He had an inordinate desire for sweets, and suffered from frequent epileptiform scizures. Being warned to desist from sweets, he moderated his indulgence. He was fitted with a correction tion for hyperopia and astigmatism, and has gone along in comfort for several years. He has lately consulted a colleague, who reports a relapse, but whether from the re-newal of his candy habit, or from a change in his refractive error, he has not since advised me.

CASE XI.—A young business man, after eating a pound of candy, usually at bedtime, almost invariably suffered from an attack of petit mal about midnight, much to the alarm of his wife. He was a mouth breather, and suffered greatly from the engorged turbinates which obstructed his nostrils. This condition was corrected, and indulgence in candy interdicted. He has since had but one or two convulsive seizures a year, where previously they occurred every two weeks. There are still two hyperæsthetic areas which should be cauterized. He had previously worn glasses, and was retested without having his neurotic condition influenced thereby.

While I do not believe that all cases of minor epilepsy can be traced to a nasal or ocular origin, the intelligent physician will undoubtedly consider it his duty to examine both these organs for possible ætiological factors.

Gastric neuroses.—These are concomitant symptoms with many ocular defects. Any ciliary irritation may cause anorexia, nausea, and vomiting. One of the most characteristic symptoms of ciliary inflammation following operation or injury is the severe vomiting which often occurs. A contracting scar in the ciliary region, or the shrinking of an eyeball over a calcareous choroid may produce prolonged gastric disturbance. On the other hand, disturbances of the extraocular muscles, persistent diplopia, or even the usual tests for heterophoria, may excite nausea and vomiting. The wearing of

prisms, muscular gymnastics, and the use of too strong lenses may set up a similar condition. It is easy to demonstrate this to one's own satisfaction by wearing such lenses for a short time. Per contra, when some high refractive error has been properly corrected, the accidental removal of the correcting glasses will often precipitate a recurrence of the gastric disturbance.

CASE XII.-A neurotic female had worn high correcting prisms for a double muscular error (hyperexophoria) for many years. If glasses were broken she had to go to bed, and in a short time suffered from profound sick headache accompanied by nausea and vomiting. Instead of submitting to a proper tenotomy for restoration of the muscle balance, she now carries several pairs of glasses with her as reinforcements in case of accident.

Dizziness, or gastric vertigo, is probably the only symptom that would naturally suggest the necessity for an ocular examination to the ordinary practitioner; and yet, as Musser says, there are many other symptoms, such as bilious attacks, periodical vomiting, anorexia, and indigestion, that may be relieved by a careful test of the eyes. Alger[™] has recently reported a case of severe abdominal pain in which low grade plus cylindrical glasses gave prompt and lasting relief. Two surgeons had made a diagnosis of either gallstones or appendicular inflammation, but fortunately for the patient the condition was correctly diagnosed by Morris as a reflex neurosis due to eyestrain. Refraction under complete cycloplegia and the wearing of the proper glasses quickly relieved the gastric suffering. The number of such cases now being placed on record should make us pause, reflect, and give the oculist the benefit of the doubt, before inflicting lavage or exploratory incision upon suffering humanity.

It goes without saying that there is a close parallelism between these ocular reflexes and those arising from nasal disturbances. In fact, I may truthfully assert that a very large proportion of gastric neuroses are of nasal origin. The hyperæsthetic areas in the upper air chambers, the lowered oxidation through lack of free breathing, and the swallowing of acrid secretions all tend to upset the digestive organs. In addition to this, nocturnal mouth breathing permits chilling of the abdominal viscera, while insidious bedroom drafts often add to the disturbance, and the ultimate matutinal condition of the sufferer is only comparable to the utter wretchedness of the poet Cowper, when he exclaimed: "I awake like a toad out of Acheron, covered with the ooze and slime of mclancholy." The morning head-ache previously referred to, the nausea, vomiting, and intermittent diarrhoea or constipation, show a marked disturbance of metabolism which only the absolute exclusion of ocular errors can differentiate as a gastric neurosis, wholly nasal in origin.

Neurasthenia.—Neurasthenia may likewise be the sequela of uncorrected eyestrain. The ocular error, however, may simply be coexistent and bear no causal relation to the neurotic condition. If this condition persists after the refraction has been properly corrected we should then turn to the nose in our search for the exciting cause. Pressure contact and obstruction to free breathing may cause lowered oxidation and faulty metabolism, and a

normal systemic balance can only be reestablished by correction of these physical defects.

CASE XIII.—A young lady, a college student, suffered from neurasthenia, intense eyepain, headache, backache, and fainting spells. There was a low grade refractive error. Muscular imbalance varied daily, from one to three degrees of hyperphoria. There was intense pressure of the left middle turbinate against a hyperæsthetic sæptum. Glasses gave no relief and were abandoned. Removal of the middle turbinate relieved all of her neurasthenic symptoms. The hyperphoria completely disappeared, and she now reads and studies with perfect comfort.

The frequency with which muscular errors disappear after the removal of pressure contact in the nose leads me to believe that this lesion may bear a causal relation to heterophoria, a question that I will reserve for future discussion. Muscular imbalance may, nevertheless, exert an irritating influence on neurasthenia.

Case XIV.—A merchant had neurasthenia following business worries. Insomnia was persistent. A long vacation had brought no relief. He came for change of glasses. He was wearing a correction for myopia, astigmatism, and presbyopia. Examination revealed hyperphoria of two degrees. The addition of a vertical prism to his glasses relieved the eye symptoms and caused immediate disappearance of the insomnia. His mental depression also improved.

Neurasthenics, however, are more liable to suffer from insomnia and sudden wakefulness when there is nasal obstruction present. This arises from lowered oxidation in the same way that we are awakened by the sudden closeness of the atmosphere in a bedroom.

Case XV.—A publisher had suffered from neurasthenia, headache, insomnia, reflex cough, indigestion, and attacks of diarrhea. He had just returned from an ocean voyage. There were obstructive lesions of both nostrils. Refraction gave no relief. Cauterization of the inferior turbinates and of the sensitive sæptal puffs brought complete relief from these neurasthenic symptoms. The insomnia and reflex cough disappeared immediately following the first cauterization, but the gastric neuroses were not relieved until after free breathing was reestablished. There has been no recurrence during the past five years.

CONCLUSIONS

The following salient points should always be borne in mind when searching for the exciting cause of reflex neuroses:

1. The eye and the nose are undoubtedly most important factors in the ætiology of reflex neuroses and should, therefore, be carefully examined and positively excluded before beginning a search for other causes.

2. Ocular and nasal reflexes possess many manifestations in common, which should be carefully differentiated at the earliest possible moment.

3. Eyestrain, whether from ametropia, subnormal accommodation, or muscular imbalance, should be carefully corrected in order to eliminate the eye as a causative factor.

4. An atrophied eyeball, with contracting ciliary scar, should be enucleated.

5. Pressure contact in the nose will always excite some reflex disturbance when any hyperæsthetic area is impinged upon, and should, therefore, be eliminated.

6. Every obstruction to free breathing should be

 Recurrence of any reflex neurosis demands reexamination and renewed search for the original exciting cause.

THE MECHANICOBIOLOGICAL STANDPOINT IN MEDICAL PROBLEMS.

By Jonathan Wright, M. D., New York.

II .- The Physical Processes in Cell Division.

If it has proved easy to find additional facts brought to light in the domain of physics and general biology, to support an electrodynamic theory of the physical processes of immunity, it will cost but little effort to throw light upon the processes of cell division and cell metabolism from the same source. I have insisted that manifestly any part of the activities going on within the colloid of cells must be of the same order as other parts and they must bear intimate relations to one another. intracellular processes of immunity are so interlaced with the intracellular processes of growth and reproduction that they in reality form one process. The segmentation of cells, resting upon the laws applicable to all spherical bodies, is necessary if they are to secure the requisite amount of surface tension to carry on their activities, by virtue of which they are said to live. Herbert Spencer, unskilled as he was in biological detail, confidently pointed this out forty years ago, and it is applicable not only to the germ cells, but to the somatic cells.1 This energy is at play in the activities of food metabolism and the preparation for future segmentation within, and in the surface activities exerted against danger from without. Therefore the consideration of the one subject is the study of the other also. When we trace the phenomena back to their underlying mechanical laws we find they merge into one another. An ever progressive differentiation of result rests fundamentally on variation due to the impingement of a varying environment, and we thus find the connection which all cell processes have with the mystery of heredity. With this I hope to be able to deal in a future communication. vision of cells has a direct bearing upon the amount of surface energy gained by the comminution of particles. To this I have referred, as demonstrated by Professor Thomson, in the previous paper of this series.2 In referring to it here, again, I but return to that common basis on which rest the differentiations to which I have just drawn attention.

How enormously the area of surface gains proportionately upon the mass of a sphere when continuously subdivided, can only be appreciated by mathematical calculation. The size of the ultramicroscopic particles in a colloid solution having been ascertained, the enormous rate at which they are darting about betrays the presence of a tremendous energy. How this comes about may be appreciated when we consider the electric charge which can be called to the surface of certain substances by attrition or other means of inducing a charge of static electricity. It has been pointed out by Biltz' that "if one divides a dice shaped cubic

[&]quot;A hold gist who has not year My Spence"s values on brobey as a foundation for future studies has been until muste, but it who has read them and has not been able to appreciate their value is describing of much greater commissions.

2.7.

centimetre of gold into one thousand smaller dice shaped pieces of 0.1 cm. lineal angular measurement the total superficies of these dice cubes will be

 $6.x (0.1) \times 1,000 \text{ cm.} = 60 \text{ cm.}^2$ i. e., sixty times the surface presented by the primary cube, but when it is divided into cubic pieces so that the lineal measurement along the angle of each piece is 10 micra, the size of some of these gold particles, which may be seen in the ultramicroscope, we get the total enormous surface 6,000,000 cm.² = 600 m.²

It is plain that if we are to suppose the surface energy is increased in the same ratio we have an energy, entirely commensurate with the enormous rate at which the particles are seen to move. From this calculation also we may understand that the adsorption, i. e., th esurface attraction of the particles for the solvent in which they lie; on the other hand, in a colloid solution, the attraction and repulsion forces—the surface tension forces—are so great that the power of gravitation is overcome and the particles do not fall to the bottom of the vessel⁵ as soon happens in emulsions, that is divisions, in a fluid, of matter whose particles are not electrically charged with surface energy. Thus we see how the cell gains in energy by division. It is the method of selection from physical phenomena whereby evolution has found a way to preserve the amount of surface energy requisite for the function of each unit of "living matter." The cell, the chromosome, and why not the molecule (?) must be to some extent subjected to this condition of extent of surface, and probably still further governed by the method of their internal structure, for instance, by the amount of chromatin in the nucleus. Doubtless the structure of the chromatin itself, and demonstrably, if we appeal to organic chemistry, the internal stereoscopic arrangement of the molecule governs through the same forces the surface tension of its unit. This is no fancy sketch, but is based on sufficient direct evidence, some of it familiar enough, to make it a working hypothesis whereby to gain an insight into many vital prob-

The chromosome of the germ cell after fertilization possesses another index of surface energy than it did before the entry of the spermatozoon, and the manifestation of its increase is seen in the vigor of the early stages of segmentation.

In this light we are to view the recent observations of Hertwig.6 "In my experiments with protozoa I remarked that those cultivated in the cold were considerably larger than those individuals of the same race which had been kept in room temperature or in thermostats of 25° C. to 30° C., that also the size of the nucleus was increased more than that of the cell body." He points out that these relations are influenced in other ways, by age, for instance, as exhaustively discussed by

Minot, but the effects of temperature are more noticeable and more easily gauged experimentally. Both Hertwig and Calkins have observed that the functional depression of the nucleus, aside from any (noticeable) change in external conditions, coincides with relative increase in size. It would be interesting to know if any difference could be observed in the nuclei of the hibernating animals, but so far as I know there has been no observation made on this point.9 It would seem that a low temperature in slowing down chemical action tends to prevent the segmentation of the nucleus, whereby it may gain in energy. We cannot forbear seeing in the advent of spring time the influence of a higher temperature upon this process, when all things burst into life.

In segmenting cells as the process goes on, Hertwig and his coworkers show that as the relative size of the chromosomes in the nucleus decreases, as compared to the amount of cytoplasm of the cell body, the time of division increases. This decrease in the relative size of the nuclear chromatin is coincident with the stage of development. Hence he supposes that the advent of the nuclear material of the spermatozoon,10 by increasing the size of the nucleus relative to that of the cell body, is directly responsible for cell division. A certain material part of the nucleus, with its attendant energy, is given off into the protoplasm of the cell body, which starts the activity of spindle formation-increases the tension of the colloid, loads its particles with a surface energy they did not before possess. This perhaps is a fair enough generalization, but, in Hertwig's contribution, alone it seems to lack the requisite amount of support in direct observation. If we are to gain this, further correlation must be attempted.

Some of it may be obtained from pathological phenomena. If division of the nucleus in physiological processes seems to be the initial stage in the effort to gain in surface energy for the organ or the individual, the formation of giant cells might seem an abortive attempt in the same direction, but we must rule out teleology. The cells make no effort, in the sense of our use of the term; they respond to a stimulus from without, a spermatozoon, or a foreign body or a bacillus or its toxine, according as the heredity of the cell, its past experience, dictates. A giant cell is not formed in that way, as a rule, if at all, and parthenogenesis would tend to disprove this method of looking at the matter were it not probable that other forces, as yet unknown, intervene to alter and check this general tendency derived from the coalescence of cells. That is not the essence of the matter. As to the giant cell the presence of a number of nuclei in the cell body is due to the confluence of the cells, and never, it is said, to segmentation. The fragmenta-

The property of the rounds that while the mass of the units in division decreases with the cube of the radius the surface decreases only with the square of the radius. Cles attract and repulse one another and never reach a condition of equilibrium, cannot be here developed, but may be found in the condition of the condition of

Popular Science Monthly.

[&]quot;It is a matter of common observation that in the north and south ranges of many species of animals, those in the warmer temperatures, for instance, quail, are considerably smaller than those individuals of the same species whose habitat is in the cooler regions. This has been worked out in a very interesting way by Vernon: Variation in Animals and Plants.

¹⁰Its greater energy is due probably to the relatively large amount of nuclear material and its small size.

tion of nuclei in the leucocytes of the specific granulomata would seem better adapted to furnish support from a pathological standpoint. Yet while giant multinuclear cells are not formed by segmentation of the nuclei they may be looked upon as the result of a sort of copulation of cells. The separate cells which have coalesced have answered perhaps to the same demand for increased energy as does the germ cell which attracts the spermatozoon that happens to swim within its zone of attraction. It is difficult to pursue such a suggestion further, because we are still ignorant of the exact way in which a change in the physical constitution of the egg cell or of the large connective tissue cell brings about the copulation.

We seem to advance a step further when we find Loeb declaring that segmentation of the cell both by parthenogenesis and by sexual division is a process of the synthesis of nuclein.12 By the influence of the spermatozoon or by that of the environment through the instrumentality of some of the monobasic fats a membrane is formed around the cell, and this is a necessary prerequisite for the mitotic process. It seems probable that lecithin is one of the fatty substances saponified or hydrolized in forming this membrane. Heidenhain remarks13 that the inability of nonnucleated pieces of cell protoplasm to form a membrane has doubtless some relation with the phenomena of artificial membrane

formation by the monobasic fats.

We again note the intervention of the lipoid substances, of lecithin especially, in vital processes. Here it may be the determining factor in fecundation and reproduction, and we have seen in my former paper the notation of the lipoids by Albrecht in fixing the basic aniline colors in the lymph spaces, close to the nuclei. I have drawn attention to fat droplets clinging around the nuclei of tonsillar cells after butter had been rubbed into tonsillar surfaces. We have seen it acting as a complement, as a fixative, for the cobra poison in the experiments of Kyes and Sachs. I have shown how quickly the oil globules sink beneath the surface of the tonsils. and recently Loeb again¹⁴ has shown that the sea urchin egg seizes upon the fat ingredient of the serum, squeezed from the bodies of worms in salt water, to start the process of parthenogenesis. There can not be an accidental coincidence in these phenomena. They are evidently all dependent upon the surface tension identical with or comparable to that which exists between globules or bubbles of fatty substances and a watery medium. If the monobasic fats enter into the chemical combinations of protoplasm they probably carry with them this means of exerting an electrodynamic influence upon contiguous matter. Long ago Bütschli and Künstler compared cytoplasm to an emulsion and more recently Dastre's repeats the simile and attempts to give it piquancy by comparing protoplasm to mayonnaise sauce. It is scarcely necessary after what I have said to insist upon the efficient mechanism thus provided for the interplay of electromagnetic forces whether they exhibit the phenomena of cell division or cell growth or cell

Nevertheless, however acceptable this idea of the physical structure of protoplasm may be it must be remembered that it lacks satisfying demonstration by direct observation. We are compelled, owing to the limitations of our power of observing vital processes when they are undisturbed, to draw inferences from the traces these processes have left behind them, these traces themselves being disturbed by our methods of making them visible.

Plainly as are granules to be seen in the resting stage of the cell under the microscope and strikingly regular as are the figures of mitosis, as we know them in the hardened and stained sections, it seems pretty certain that these bodies in life are not solid bodies at all. They are local states of a perfectly fluid medium distinguished one from another by differences in the local dynamic index. Such areas of distinctive potential as exist seem to have a spherical shape (centrosomes) and when the cell is hardened and stained the lines of force between them are revealed by a coagulation of the fluid. This I have stated before, but I find it compactly expressed by a more competent authority. Heidenhain's concludes that "such structures as chromatin granules, centrioles, and chlorophyl kernels have never been demonstrated intra vitam. So far as the genuine protoplasm microsomes are concerned their noncoloring properties depend upon the fact that they are not sharply limited and defined individual bodies, but only thickened places of the living plasma, with which they are in complete somatic continuity." Even by intra vitam staining we throw upon the delicate mechanism of the cell an unaccustomed burden in the adsorption of the color granules which allow us to see something of the internal workings. How much these dead flies in the cobweb, this junk in the cogs of the vital mechanism, how much these foreign bodies each with its own index of surface tension have marred the picture, we do not know.

If we are compelled to admit the probability that the means we adopt to obtain an intra vitam demonstration disarranges the processes, how misleading must be the results of the cataclysm which wrecks the whole labile structure by the coagulation of fixing, hardening and staining. When the action halts. at once there is brought into play the forces of nature which by disintegration prepare the dead matter for removal,-for the sweeping away the dust into which the gossamer machine has been resolved. The action of various enzymes in dissolving proteids has been shown to persist even after the tissue has" been hardened in Zenker fluid and alcohol.

My space being nearly exhausted, I cannot quote. as I should like, from some experiments of Lillie"

which go far to demonstrate that the belief that the karyokinetic figure is caused by the radiation of lines of force from the centrosome, chains of force according to Hartog, is the correct view to take of it. The displacement of the centrosome by centrifuging the egg of a certain annelid (Chætopterus), leads to a corresponding deformity of the mitotic figure, the disturbance taking place during the activity of an unfertilized segmentation.

What we see under the microscope, then, we must regard as nothing but the footprints left behind in the march of events, the streaks and grooves left

behind by the electric current of life.

Postulating the fluidity of protoplasm, we are enabled to come within view of an era in which the advancing strides of mathematical progress will enable future workers to apply a precision to the exposition of the workings of vital processes, of which until lately biologists have scarcely dreamed. Lamb10 suggests that the figures of mitosis so strikingly suggestive of electrodynamic action in so many particulars, owe their apparent departure from what we know of the laws of magnetism, to the influence of polar attractions and repulsions, alternately exhibited by polar bodies pulsating in a liquid medium in accordance with the recent work of the V. Bjerknes.20 In their work the mathematical results arrived at in finding an equation for the action of one pulsating or whirling or advancing body in a homogeneous liquid upon another body of the same nature, is of a kind which can be critically examined only by one familiar with the modern state of mathematical science. So far, however, as can be gathered by the aid of a limited familiarity with the field of physics, it appears that the interaction of one body upon another at a distance through the medium of currents in the fluid bears a striking analogy to those interactions of one electrified body upon another at a distance through the medium of electrical currents in the ether. The difference in the terms of the equations and in the results of their functions seem due solely to the difference in the physical properties of water or other real fluids and those of the ether as theoretically formulated by physical science. Thus for instance, when we read "Spherules pulsating alike attract one another (in the fluid): those pulsating nonsynchronously repulse one another" we are reminded at once, it is true, of the principles upon which wireless telegraphy has been founded, but we are still more reminded of our problems in mitosis. The "pulsating molecule of life," a struggle with syntax to subordinate complex phenomena to our finite comprehension, the radiation of lines of force from the centrosome and the phenomena just referred to, by these attempts at correlation, begin to assume a suggestive significance which we cannot ignore. It seems apparent then that to the changes constantly wrought in fluid protoplasm we must apply not only the laws of electrodynamics but the laws of hydrodynamics.

44 WEST FORTY VINTH STREET.

THE PURPOSES AND OBJECTS OF MORBIDITY STATISTICS AND THE METHODS OF COLLECTING THEM.*

BY ASSISTANT SURGEON GENERAL J. M. EAGER, United States Public Health and Marine Hospital Service,

Sickness statistics are, from a sanitary and economic point of view, of greater importance than death statistics. As a gauge to the severity of a disease, as a measure of its damage to society, and as a guide to sanitary action, death statistics are fallacious. They can be considered only as a part of the bookkeeping by which sanitarians determine how well their work pays. Death returns tell nothing of the great mass of common diseases, because many common diseases are not fatal. It has been said that "persons rarely die of the disease from which they suffer." Diseases of the heart and bloodvessels, cirrhosis of the liver, and Bright's disease often terminate in tuberculosis; many diabetic patients die of acute pneumonia. On these subjects the mortality tables are silent.

The prosperity of a community is greatly influenced by the number of persons sick and the character of their illness. These variations of public health are not necessarily indicated in the mortality returns. In an address on sanitary reform delivered many years ago, Lord Lyon Playfair pointed out that the registration of deaths represented the wrecks which strewed the shore, but gave no account of the vessels which were tossed by the billows of sickness. Sickness statistics would, however, tell of coming storms and enable us to trim our vessels to meet the

tempest. Death statistics furnish no information whatever in the case of many diseases which, though fearfully capable of making many lives miserable and greatly diminishing the effectiveness of their victims' work, seldom prove fatal. Trachoma, with its train of ills, is a type of such disease. Sickness may be spread throughout a community, the schools may be closed, business almost suspended, and an exodus of panicstricken persons take place with no appreciable impress on the death returns. In 1873, there was an epidemic of dengue at New Orleans, and it is estimated that 40,000 persons contracted the disease. At Galveston, in 1897, within two months, 20,000 people were attacked by the same disease. Such prevalences would not be indicated by the death returns, because, in dengue, death rarely occurs except in patients already weakened by other disease.

Mortality returns give us the relative death rate for sex, age, color, etc., but are mute as to the relative incidence of disease among the different classes of the population. Scarlet fever, for instance, is much more fatal in cold climates than in subtropical places. Measles may be very prevalent among children in the north with no extraordinary showing on the death records, whereas in armies and in the well known epidemics in the Faroe Islands in 1846 and in the Fiji Islands in 1875, the mortality from measles was appalling.

The fatality of different diseases varies under

[&]quot;A low Far witten of the Laures of Mitosts, by Arthur B. Laush The sured of Experimental Zoolog, vor. November, 1907. P off to a no he Krafte, 2 vols, 1912

^{*}Read before the Section on Vital Statistics at the meeting of the American Public Health Association, Winnipeg, Manitoba, August.

different circumstances. A disease with a low mortality rate at the time of its greatest diffusion may be a peril because of the possibility of its becoming more deadly later in its course. On the other hand, death returns in the case of a highly mortal but slightly diffused disease may give rise to false inferences as to the extent of the prevalence.

"Those who see scarlet fever by the thousand," says a recent writer, "are well aware that any reduction in case mortality that can be hoped for by improved methods of treatment will be too slight to be shown conclusively by working with death rates."

It may be confidently stated that, as long as the amount of sickness remains a matter of guesswork founded on statistics of disease in hospitals, or among special classes of the population, or on such indirect information as death returns, no satisfactory knowledge of the economic relations of disease can be had, and no battle with calculable results can be made against it.

PURPOSES AND OBJECTS OF MORBIDITY STATISTICS.

Aside from the more evident uses of notification so that prompt action may be taken against the spread of communicable disease, a complete system of sickness registration would serve many useful ends. With the aid of such information it would be possible to institute accurate comparison between the health of urban, suburban, and rural districts; the relation of diseases to climate, the seasons, altitude, and latitude; the effect on health of dwelling on soils of different character, and in the vicinity of various natural bodies of land and water. Undoubtedly much light would thus be thrown on many common but not highly fatal diseases such as rheumatic diseases, a class of illness which causes incalculable public loss and private suffering.

Observation on the sensitiveness of public health to weather conditions depends largely on our knowledge of the prevalence of sickness. The same may be said of the disease producing effects of local conditions, such as overcrowding, occupation, proximity to hospitals and unhealthful industrial plants. Some of the remediable drawbacks of farm life would

be brought more prominently to light.

The relation of the predominant diet to disease in given districts is a subject depending on morbidity statistics. For example, statistics are needed in the case of pellagra, a disease of immense economic importance in Italy, which recently has been reported in different localities in the south of the United States.

Information is needed of the relation of trades to lead, phosphorus, arsenic, and other poisoning, as well as to such other diseases as anthrax, glanders,

and actinomycosis.

It is within the scope of such statistics to procure precise knowledge of the fatality, and hence of the prognosis, of different diseases, and to determine what has been called the "expectation of sickness," including the average liability to sickness and the average time lost per annum on that account. This information is of importance in establishing the premium rates of sickness insurance. It would also include an exact knowledge of the duration of attack of different forms of disease. Such statistics, especially as regards injuries, are of great interest in

relation to employers' liability, a subject attracting much public attention at the present time. By registration, our knowledge of the economic aspect of sickness would be improved and the extent determined of the loss of work from different forms of disease—in other words, the public cost of given diseases. A means would be furnished of keeping tally on the efficacy of preventive measures and of reckoning the value of the different classes of therapeutic institutions and of health resorts.

METHODS OF COLLECTING SICKNESS STATISTICS.

Three methods of collecting sickness statistics have been proposed: 1, Enumeration; 2, estimation; and 2 registration.

tion; and, 3, registration. Enumeration .- An attempt was made in the United States Censuses of 1880 and 1890 to learn the number of those who were on a given day so sick or disabled as to be unable to pursue their ordinary occupations. Similar attempts had been previously made in Ireland, Tasmania, and Australia. The result of these experiments was not very productive of valuable statistical information, and the attempt was abandoned in the United States, no such interrogatories being required in the taking of the last census, 1900. It was at least learnedthough the figures were no doubt too small-what a great proportion of the population was constantly disabled from disease from which no satisfactory statistics were available. Thus, in 1890, the figures obtained showed that, in the northeastern States, out of each 100,000 of population on June 1st, 1,684 were affected with sickness or recent accidents, the greatest proportion being found in the State of Vermont (3,292), and the least in Maine (1,291). In the three southern States for which figures were given, the greatest proportion of sickness was found in Virginia (1,991), and the least in Alabama (1,754). The aggregate of nine great cities in the United States gave a ratio of 1,002.

Estimation.—The pioneer in England in the actual practice of obtaining sickness statistics was Dr. B. W. Richardson, who, for several years toward the middle of the last century, maintained without official support a system whereby such information was obtained through the agency of forty-four observers in all parts of Great Britain. The system of collecting sickness statistics by estimation, of which Dr. Richardson's method was an example, depends upon gathering data supposed to be representative and deducing therefrom conclusions as to the prevalence of disease. A similar system, covering a considerable number of diseases, was instituted in Massachusetts in 1875, and has since been tried elsewhere in the United States without statistical results of much importance. In Massachusetts, the State was divided into seven sections having distinctive topographical character, such as the "hill country," the "valley section," the "island section," etc. Physicians were selected in each section to perform the part of observers, and special reports were gathered from medical institutions.

A system of representative averages of the nature of those mentioned has been specifically investigated by a sanitary board of the Public Health and Marine Hospital Service, with the conclusion that the board was unable to recommend the plan, believing that

the element of judgment enters so largely into it as to render the results in too great a degree a matter of conjecture.

Registration.—At the beginning of the eighteenth century, a member of the British Parliament suggested to that body that the registration of certain diseases be required by law, declaring that a great saving of life among rich and poor would result. Registration of disease in Great Britain, though warmly advocated by the British Medical Association and by many prominent medical men and economists, did not become a law anywhere until 1877, when the first local act for enforcing the compulsory notification of the principal contagious diseases went into operation in Bolton, Lancashire. The adoptive enactment of the Notification Act in 1889 was followed by the adoption of notification of the chief infectious diseases throughout England. England was in this respect behind Belgium and many parts of Germany, where the compulsory notification of infectious diseases has been in force for nearly a century. Germany has also, for the last thirty years, maintained a fine system of hospital statistics of general diseases as well as infectious diseases, including alcoholism, rheumatism, injuries, idiocy, lunacy, old age, and diseases of the eye. In the United States, registration of communicable diseases has become compulsory by law in many States and cities, but, while in some places the returns of certain of these diseases are apparently quite complete and have been most useful for directing preventive measures, it cannot be said that the mass of morbidity returns is of great statistical value.

There is no doubt that the only feasible plan for the collection of morbidity statistics is by registra-Their collection in the United States should be undertaken by the different States. The following is an extract from a report made by the writer on the method of collecting morbidity statistics in the State of Pennsylvania, where the plan was adopted after the most careful study of the subject:

"Under the provisions of an act of Assembly, April 27, 1905, regulations have been promulgated requiring all physicians practising within the limits of the State to make immediate report of certain diseases occurring in their practice. In the case of cities and boroughs, the report is made to the secretary of the board of health of such cities and boroughs; when occurring within the limits of a township, the report is made to the county medical inspector, and also to the Department of Health at

"Notification is required in the case of twentynine diseases, namely: Actinomycosis, anthrax, bubonic plague, cerebrospinal meningitis, chicken pox, cholera, diphtheria, epidemic dysentery, erysipelas, German measles, glanders, hydrophobia, leprosy, malarial fever, measles, mumps, pneumonia (true), puerperal fever, relapsing fever, scarlet fever, smallpox, tetanus, trachoma, trichiniasis, tuberculosis (form required to be specified), typhoid fever, typhus fever, whooping cough, and yellow fever.

The reports are made on a standard postal card, giving the date of the report, the full name of the patient, occupation, nativity, age, sex, color, and address of the patient, including, if in a city or borough, the name of the street and the house number, and the name of the city or borough and county; if in a township, the post office address of the patient, the name of the township and county, the name of the disease, the date of the onset of the disease, the name and occupation of the householder in whose family the disease has occurred, the number of children in the household attending school, the name of the school or schools, and the name and address of the physician making the report. In addition to the regular reports, special immediate reports by telephone or telegraph of all cases of smallpox are required. The city and borough boards of health are required to report weekly to the State Department of Health on prescribed forms. A report is also made for any fraction of a week occurring at the end of the month, so that the first weekly report in any month begins with the first day of the month.

"Hospitals and all other institutions for the care of the sick are required to make special monthly reports of the twenty-nine communicable diseases enumerated. These reports of institutions are carefully checked in the State Department of Health to prevent duplicating with local reports.

"There is also a special form for the weekly report of the city of Philadelphia for the reason that in that city the street name and house number as well as the name of the patient are reported.

"Daily reports of communicable diseases in townships are made to the State Department of Health, confirmatory of the reports of cases forwarded directly on postal cards by medical practitioners.

"Weekly summaries of communicable diseases in cities, boroughs, and townships are also forwarded

to Harrisburg.

"The reports of the twenty-nine communicable diseases covered by regulation are recorded in registers at the State Department of Health, and the data are arranged by the aid of punching machines for tabulation in the annual report of the department. Defective cards are returned for completion. In every case of death from any of the twenty-nine diseases in question an inquiry is made to ascertain whether the requirements regarding notification of the disease have been complied with.

Morbidity returns in order to reach the greatest perfection as statistics should be gathered from the largest possible territory. In the United States the data collected in the different States should be brought together, classified, and published at Washington, so that the returns of one State may be conveniently available for the information of other States, and with an ultimate view to a uniform sys-

tem of international morbidity statistics.

At the present time morbidity tables as well as untabulated morbidity reports covering the principal communicable diseases are printed weekly in the Public Health Reports, a publication issued by the Public Health and Marine Hospital Service. The reports of yellow fever and plague, when these diseases occur within the United States, are believed to be as complete as it is possible to make them. The smallpox returns are constantly improving. data used in these morbidity tables are derived from reports of officers of the service, from information received weekly on blanks sent to all cities of over 10,000 population in the United States, and from official reports of diseases recorded in towns and States where registration of certain diseases is required by local or State statutes.

The movement for the systematic collection of morbidity statistics, having for its ultimate object the registration of every disease of importance from a sanitary or economic point of view, should be begun by effective laws in every State for the prompt reporting of all virulently epidemic and actively communicable diseases. To these should be added from time to time, as the public becomes educated to the importance of their registration, the more remotely communicable diseases and diseases depending on remediable local conditions. So it might be hoped that finally the advisability would become evident of adding to the list all diseases and injuries of economic interest. The prompt and uniform reporting of sickness depends much for its success on the enlightened public spirit of medical practitioners. Even more than in the case of death statistics, the element of accuracy in diagnosis becomes a factor that cannot be disregarded in drawing conclusions from the returns. The most important element in bringing about such a desirable result as a universal system of sickness statistics is an active educational campaign carried on not only by the public authorities, but by every person interested in the public welfare.

THE SCHOOL CHILD. By J. W. Van Derslice, M. D., Oak Park, Ill.,

Instructor in Pædiatrics, Rush College; Attending Physician, Central Free Dispensary; Consulting Physician, Jackson Park Sanatorium.

At a meeting of the American Medical Association, held at Atlantic City in 1907, there was appointed a committee to investigate the "present status of the school child," upon which committee the author was appointed for the Middle West. The work of this committee entailed an enormous amount of correspondence with the teachers, principals, and superintendents of this territory, the results of which are the basis of this paper.

The subject of stress and strain in the school child embraces a wide variation in the viewpoints of those interested in the product of our public schools. As the State has taken upon itself the education of all children between the ages of six and fourteen years, society has an interest in seeing that the child is educated along lines which be of economic value to the State in the development of a citizenship of a worthy type.

The attention of the State and educators is concentrated upon the small part of child education, the development of the intellectual capacity. viewpoint of the parent is as diversified in almost as many channels as there are parents. The custom of judging the school by comparing the work of the pupils by the alleged work of the parent at a corresponding age is as unfair to the child as it is to the school. The attitude of the physician should be that of adviser rather than critic; to try to amalgamate the cross purposes of the interested parties to the better development of the child. If there is forgetfulness of character formation, or an absence of interest in the physical welfare of the child, then the medical profession should demand that proper safeguards of these qualifications be thrown about the child, as education is the equipment of the individual for service, and if the mere possession of

useful facts is gained at the expense of illhealth, mental inervation, or moral blight, the price is too

great to pay.

Some of the contributing factors of stress and strain of the school child lie in the child, as, hereditary dyscrasia, physical, mental, and moral condition of the child, the home environment, the condition of the child as a result of the artificial life in large cities, the many chronic disorders of nutrition and digestion, the quantity and quality of food ingested, the frequent lack of intelligent parental oversight, the want of sympathy between parent and teacher, the need of sufficient sleep, employment for economic purposes or for the care of younger children outside of school hours, absences from trivial causes, social distractions, these all combine as factors in the burdens of the school child.

In the school are found the conditions of the school building and the school room, the sanitation of the school, improper desks and seats, lighting facilities, the ventilation, the character of type in textbooks, and the glazed paper of the school books, the use of free textbooks, the number and frequency of infectious diseases, hours of confinement within the school room, lack of proper recreation periods, the school curriculum and the lesson schedule; these with many others have a place in the causes of stress and strain on the school child.

The constantly recurring cases of physical and mental lassitude occurring in the school child should not be dogmatically set down as caused by the amount of work required by the school, but rather a careful investigation of the foregoing causes should be made and the recommendations for correction along the lines affecting the individual.

The hygiene of the home is largely beyond the influence of the physician except in individual cases. but by education of the masses to a proper appreciation of the benefits of the simpler rules of hygiene much good may be accomplished. In the homes where better things may be expected there is great need of education along lines of sufficient sleep for the child, a regulation of the duties and hours that there be no need for the hasty breakfast of a cup of coffe and a piece of bread gulped down with one eye on the clock in fear of being tardy. For the amount of sleep required during the developing period the following should be considered the minimum: Five years, thirteen and one half hours; six years, thirteen hours; seven years, twelve and one half hours; eight years, twelve hours; nine years, eleven and one half hours; ten and eleven years, eleven hours; twelve and thirteen years, ten and one half hours; fourteen and fifteen years, ten hours; sixteen and seventeen years, nine and one half hours; eighteen and nineteen years, nine hours. The importance of easily digestible food, with an interval of rest to follow each meal, are points needing special emphasis. The greatest abomination of the school system is the school store with its cheap candies and sweetmeats.

The life of the city child, with its freedom from the chores of the country bred child, is a factor in development that must be taken cognizance of. This lack of regular duties and responsibilities has much to do with the lessened self reliance, self determination, self control, and self direction of the present day child. The necessity for employment for economic purposes outside of school hours affects a large number of pupils in the higher grades; it was found that in the rooms above the sixth grade there was usually from ten to fifteen per cent. of the pupils who were thus regularly employed; and the kind of employment was such that would be likely to throw him into contact with vicious associates.

The lack of harmony that exists between many parents and the public school, which is fostered by much undue criticism that is now in vogue by the lay press, and the careless assigning of all cases of stress occurring in the school child to the shortcomings of the public school system, react upon the child both in regard to the school discipline and the character of work performed. This want of a proper regard for the school and what it stands for is oftentimes the cause of the many absences for trivial causes.

The social distractions during the school life have a greater demoralizing influence than is realized; this is especially true at certain seasons, as Christmas, Easter, Children's Day, etc. * The testimony of many teachers is that "the attendant excitement affects the quality of the pupil's work for weeks," both previous and subsequent to the event.

The sanitary conditions in many of the schools is "impossible." In but few of the schools is there any adequate apparatus for the proper ventilation of the school room, and in many of the rooms the only means of ventilation is to open the door or windows. The appearance of the school room is bleak and uninviting. The desks and seats are not suited to the size of the child. There are now usually supplied two sizes of seats and desks in each room. There should be supplied, in addition to this, a number of adjustable seats and desks which should be adjusted to the pupil by a competent supervisor.

The effect of poor light, with the poor print and glazed paper combined with the eyestrain of blackboard work, is but too familiar, and the constantly increasing proportion of children with refractive errors as the higher grades are reached gives evidence which is unquestionable.

The enormous number of children who suffer from one or more of the infectious diseases is so great that it is now taken as a matter of course that the school child should be thus attacked. The fact that these diseases are preventable apparently is of little moment, judged by the demeanor of the various school boards. The walls of the school are uncleaned from year to year, and the memory of man goeth not back to the time when some of them were kalsomined. The floors are not scrubbed, and the desks and seats are not washed for months. Fumigation is only done after the most flagrant infections of scarlet fever and diphtheria. The common drinking cup is furnished in place of a hygienic fountain or individual cups. In the use of free textbooks is found another of the commoner modes of infection. The average life of a book is four to live years, and each book is used by several pupils; these are neither fumigated nor destroyed unless at the home of a pupil where there is either a care of diphtheria or scarlet fever.

The schedules of the various grades call for a

recess during the morning and afternoon sessions, but as it is found that there is no provision made for the protection of the pupils during stormy or inclement weather the recess at such times is omitted and the child is confined during the entire session. It is a necessity for good health that these children have the benefit of fresh air and freedom from restraint for a short interval, and there should be provided a covered area for such times as it is needed. It is found that in many of the schools there is no other playground than the street, and, strange to say, the more congested the district, the less the playground furnished. It should be an essential of every school to have a playground of sufficient size to accommodate the entire school. The judicious use of the playground is of great value in the building of character.

The number of pupils in a room is far too great. It is not uncommon to find upward of seventy pupils in a room under one teacher. This is a crime against both the teacher and pupil, as it is a manifest impossibility for a teacher to do justice to such

The burden of the criticism of the public school is the overcrowding of the curriculum. This criticism of too many studies and too much demanded is met with, both from within and without the school system. Many educators quite severely criticise the present curriculum. The State insists upon the attendance of every child, for five or six hours a day, five days a week, in the public school. the outcome of this compulsory education the school is gathered from all races, all strata of society, all conditions and customs of living, representing all sorts and varieties of tastes, talents, and capacities; and for this heterogeneous mass the educator must formulate a system of education that is suited to the individual. That the system developed under such unfavorable conditions is measurably successful is evidenced by its product; as samples, take the American medical and scientific men of to-day who were its graduates of a few years ago.

There is now in the curricula of the various schools evidence of transition. In periods of transition there is not stability. The element of stability has not been present since the days of the three "Rs". The practical ideal of education, that the school must fit the child for something, is the main cause of the changes in the curricula. In the rapid evolution of commercial and social life there arose a demand for more than was compassed by the rudimentary branches, and the spreading out of the curriculum was a necessity. With the centering of large masses of population in the cities there arose a need of a cultural as well as an intellectual side of education, with the result that the school child of to-day is better informed upon many subjects, but has not the mastery and thoroughness of a given subject that developed the initiative, self reliance, and the ability for individual work so common under the old method. In the multiplicity of subjects there is of necessity a tendency toward superfluity. The requirements of the curriculum are such that the teacher does not have the time to teach as she should, but she must try to instill into the child a certain definite number of facts rather than take her place as a real teacher to bring out of the child the best that he has.

The overcrowding of the curriculum is due to three causes: I, Every child must take all of the work, regardless of personal or individual need; 2, whatever the last generation had must go into the curriculum of the present one; 3, domination by

the colleges.

The curriculum is fitted to the average child in regard to his ability to average work. That the child must take all the work as laid down, regardless of his condition, adaptability, or environment, is an error. It would seem advisable that the curriculum for each school should be made by the teachers, principal, and superintendent, as they should be in a position to best judge the needs of that particular school. That it is compulsory for the pupil taking private instruction in one or more of the school studies to take the same courses in the school seems a waste of effort.

The domination of the curricula of the public schools by the schools of higher learning is of questionable advantage when it is considered the very small percentage of the pupils that enter the colleges. It is obvious that to build a curriculum to meet the demands of the colleges rather than to fit the child for his life's work is not carrying out the needs of the average child, and in this lies one of the prominent reasons for the large number of pupils who drop out of school so soon as the law allows, because of this seeming impracticability of the courses. It is beyond all question that the grammar school does not give the appetite for learning that could be developed were the curricula so arranged as to equip the child for the technical work in which it was probable he would engage.

The most frequent criticism is of the special studies and the special supervisor. The question of the value of the culture studies is not properly understood. In the public schools of the large cities there are from seventy to eighty per cent. of the pupils that are foreign born or the children of foreign born parents. In quite a considerable proportion of these pupils the only real culture that they are apt to receive will be from the public schools, and as it is the psychological period, that period in the development when there is an unfolding, that these studies are given, it is the physiological period for the imbedding of real culture. Take the domestic science course, the immediate benefits of such a course in the poorer districts will be that there will be a demand for the better foodstuffs in the families coming under such influence. There can be no greater benefit accrue to the congested districts of the large cities than that the girls shall have a knowledge of foods, their values, modes of preparation, and the art of making tasty the commoner foods. The crying need of these districts is for better cooks, and if these girls of necessity must go from the school to the factory, to wifehood, where can they get a working knowledge of the duties of the housewife? So with the other culture studies as music, drawing, and literature, it would be a step backward to take away the taste of literature that these children receive. There should be a decided effort to inculcate in these children a taste for good literature; it is not that they do not read, but that their reading is ill advised, and a little painstaking effort might lead them along the better way. The criticism of the drawing and writing lessons should lie in the manner of teaching. It is self evident that it is impossible to have a certain set of lessons fitted to the sixty or seventy pupils in a room, and great harm arises from the apparent aim of the teachers in the excellence of production that these products may be exhibited for the benefit of fond parents, regardless of overstrain in the child, rather than the developing of the child. The development of the child in the lower grades is such that the movements should be confined to the coarser free hand type. The finer coordinations necessary for the detail of either drawing or writing must result in harm to the child if carried to the point of fatigue.

Manual training is of value in developing self reliance and self determination. The carrying out of a task to completeness must result in great moral benefit. To interpret this course to mean a trade school is an error; it should be used as a method for development, as during these years there is an innate desire to create, and in such a course there is the desired element of creating the finished product.

In the arrangement of the lesson schedule there is a total disregard to the attention period. length of time that a child can profitably apply himself at the various ages to a given subject has been 'amply demonstrated by Gilbert, Chadwick, and oth-The public schools have generally the same lesson periods for all the grades. The schedule of lessons is made up with only two points in view: To fit in with recesses and to have the harder studies early in the sessions. A rather constant factor which aggravates this prolonged attention period is to have the study hour for the course immediately precede or follow the recitation, thus incurring a doubling of the period of attention to a given subject. While teachers as a rule recognize the difficulty of holding the attention for a full lesson hour, the cause as a physiological factor being the deterrent is not taken cognizance of.

The schedule should be so arranged that no period shall be longer than fifteen minutes for children under nine years of age, twenty minutes for children nine and ten years of age, and twenty-five minutes for children eleven to fourteen years of age.

155 NORTH SIXTY-FOURTH AVENUE.

ANCIENT GREEK MEDICINE.*

BY CHARLES W. SUPER, M. D., Athens, Ohio.

It is well known that science had its beginnings among the ancient Greeks, which does not necessarily mean the inhabitants of Greece proper. It was they who first displayed what we may call scientific curiosity. They traveled into other countries in quest of information. They observed and recorded phenomena and tried to explain them. Their essays were often childishly crude, but they were in the line of progress. We are frequently surprised at their shrewd inferences and at the close proximity to important discoveries which their guesses indicate. A boy may not know one tenth as much as his father, but if he has the habit of observing and reflecting and drawing conclusions

^{*}The reader is also referred to two articles in the P-pular Serence Monthly for September, 1005, and May, 1007, entitled Physicians and Philosophers, and Sight and Seeing in Ancient Times.

he will eventually surpass his parent, if the latter is content to follow tradition unquestioningly. Stephenson's Rocket and Fulton's Clermont bore little resemblance to their successors of a hundred years later, yet they embodied the essential principles on which all subsequent steam engines were constructed. Hence, although the Egyptians and the dwellers in Mesopotamia, had accumulated a large stock of practical experience, it was only in a small measure fruitful. That the Greeks derived little from them is indirectly shown by the fact that those who lived in Italy were as far advanced, in some respects farther, than those who dwelt around the shores of the Ægean Sea. The ancient historians tell us that in Egypt physicians were paid by the state and were required to give their services gratis. In their practice they were bound to follow a collection of rules formulated by a distinguished body of physicians in early times; otherwise they rendered themselves liable to the death penalty. Later, however, they were permitted to vary their treatment on the third day, but at their own risk. Herodotus reports that in Egypt each physician treats a single disease only, and that the country swarms with medical practitioners. Egyptian medicine is referred to by Jeremiah in the words: "O virgin daughter of Egypt, in vain shalt thou use many medicines."

The story of Democedes as told by Herodotus,

even though it may be somewhat colored by national prepossession, throws an interesting light upon the esteem in which Greek physicians were held in the time of the great Darius as contrasted with the Egyptian. The king, when leaping from his horse, sprained his foot so severely that the ankle bone was forced quite out of the socket. As the Egyptians were reputed to be the best skilled physicians in the world he always kept several about the court. To these he had recourse; but they twisted his foot in such a violent manner that they only made the matter worse. For seven days and seven nights the king was unable to sleep owing to the severity of the pain. He then happened to hear of one Democedes, of Crotona, who was the slave of Orœtes; this man he accordingly ordered to be brought into his presence. When he made his appearance he was still loaded with fetters and clad in rags. Upon the king's asking him whether he understood medicine he answered in the negative, fearing that if he made himself known he would never see his native land again. Darius, who had evidently heard of him before, suspecting that he was not acting in good faith, threatened to put him to the torture. Whereupon Democedes replied that he had no thorough knowledge of the art, but owing to his having lived some time with a physician he had acquired a slight smattering of it. The king, nevertheless, put himself under his care, and "by using the remedies customary among the Greeks, and exchanging the violent treatment of the Egyptians for milder means, first enabled the king to get some sleep, and then in a very little time restored him altogether." Democedes showed his hu-manity by interceding with Darius for the lives of

the Egyptians who had formerly had the care of the king, but whom he was about to impale because

they had been surpassed by a Greek.

A short time after, Atqssa, the wife of Darius, had a boil on her breast. This broke first, then began to spread and increase. As long as it was of no great size she concealed it for shame; but when it became worse she sent for Democedes. He at once promised to cure her upon condition that she would grant him one request, which he assured her would be nothing she would blush to hear.

Preceding the account of these adventures Herodotus relates that Democedes left his home in Crotona and sailed to Ægina because he could no longer endure the ill usage of his father. "There he set up in business, and succeeded the first year in surpassing all the best skilled physicians of the place, notwithstanding that he was without instruments and had with him none of the appliances needful for the practice of his art. In the second year the state of Ægina hired his services at the price of a talent; in the third the Athenians engaged him at a hundred minæ; and in the fourth Polycrates at two talents. It was in no small measure from his success that the Crotoniats came to be reckoned such good physisians; for about this period the physisians of Crotona had the name of being the best, and those of Cyrene the second best in all Greece.' It should be remembered, however, that only two of the above named cities were in Greece proper, although both were Greek cities, the one being in Italy, the other in Africa.

Egyptian medicine, like Egyptian civilization, as a whole, had very early reached the stage of stagnation. To us it is a completed product to which nothing was added in later times. In the history of the past we frequently meet this pathological condition of the human psyche. There is no ex-

planation of this curious phenomenon.

The astonishingly accurate knowledge of anatomy shown in the Homeric writings, especially in the Iliad, a "poem of glorified slaughter," has often been remarked. Here we find all sorts of wounds inflicted on almost every part of the body by many different kinds of weapons, but of this number only seven are so vaguely given that a skilled anatomist would be unable to determine their character. As this poem, in part at least, goes back more than ten centuries beyond the Christian era we are constrained to wonder how the authors obtained the information. Perhaps the wonder is not so much that the knowledge should have been obtained as that it should become a matter of record. Two surgeons, Machaon and Podaleirios, are mentioned with honor in the Iliad, the former about a dozen times, the latter twice, but only in connection with the former. Both are sons of Æsculapius; both are not only skilled in the medical art, but are also valliant spearmen. Both are princes and consequently men of mark among their fellows. There is only a single mention of the veins in Homer. Attention has more than once been called to the fact that the description given here corresponds exactly with that given by Hippocrates. "And Antilochus watched Thoon as he turned the other way, and leaped upon him, and wounded him, severing all the vein that runs up the back till it reaches the neck, this he severed clean, and Thoon fell on his back in the dust." The drastic surgery of the Homeric age is strikingly exemplified in the following passage: "Then he stretched him at length, and cut with a knife the sharp arrow from his thigh and washed from it the black blood with water. And thereon he cast a bitter root, rubbing it between his hands, a root that took away pain, and ended all his anguish, and the wound began to dry, and the blood ceased." Persons who have read accounts of the surgery of the primitive races will not be surprised at the statements found in Homer. I recall an account of the Cæsarean section witnessed in Uganda by Dr. Felkin, of Edinburgh, and published by him in a pamphlet. The patient was first partially stupefied with banana wine. During the operation the flow of blood was stopped with a red hot iron, which was, however, applied very cau-During the entire operation she uttered tiously. no cry, and an hour after its conclusion she had entirely recovered from the shock and was on the way to complete restoration. While engaged on the case the chief surgeon made free use of incanta-To a highly intellectual person chanted words are meaningless, but to people whose entire life is governed by their emotions the case is widely different. We need only to reflect how the writer of Genesis conceived the creation of light. "And God said, Let there be light, and there was light."

In those early days the pharmacopœia was largely made up of vegetable productions of various kinds. Oil, wine, and vinegar were medicaments frequently employed. The case can hardly have been otherwise at a time when chemistry was virtually unknown. It would seem from the passage quoted that plants having certain well established medical properties were kept near at hand in a dried state, as otherwise the language of the poet is hardly intelligible. Women are credited with especial cunning in this branch of medical lore. We read elsewhere that "fair haired Agamede knew all the drugs that the wide earth nourisheth." sorceress Circe is likewise reputed to have been an adept in the use of plants possessing unusual medicinal virtues. The reader need hardly be reminded that a similar belief exists in many parts of the world, including the United States. Strictly speaking, Homer makes no mention of internal disorders. The Iliad opens with a brief reference to the pestilence sent by Apollo into the Greek camp. It first attacked the dogs and the mules, but later the men

Circe turned the bodies of Ulysses's companions into swine, but she could not change their minds nor prevent them from realizing their degradation. The transformation was accomplished by means of a magic potion and the stroke of a wand. After Bellerophon had incurred the enmity of the gods he wandered alone, devouring his own soul and avoiding the paths of men.

That the influence of the mind upon the body was early recognized by the Greeks is evident from the directions given by the priests of Æsculapius to the patients who resorted to his temples for the cure of the maladies with which they were afflicted. But as they were not conversant with psychology, as it is now understood, the numerous cures reported are attributed to external agencies, not to autosuggestion and subjective mental states. In

the earliest times as described by Homer all psychic agencies are external. The Homeric heroes are impelled to action or to refrain from action by the direct interposition of the gods. In the second book of the *Iliad Zeus* sends a baleful dream to Agamemnon, inciting him to undertake an enterprise that was doomed to failure. In the first book Athene seizes Achilles by his golden hair and prevents him from drawing his sword to smite Agamemnon. On the other hand, the dreams which were sent by Apollo to Æsculapius came to enlighten, not to deceive. There is, furthermore, little doubt that the voice of the Lord so often spoken of in the *Old Testament* is to be explained in the

For the Greeks Socrates stands on the dividing line which separates ancient and modern modes of thought. To him the actual state of the case was not fully clear. He recognized an inner prompting, or, rather, an inner restraint; but he still regarded it as a divine voice. He felt strongly that there were certain things he ought not to do; he did not realize that it was a part of himself that was acting upon another part. In the Iliad, Cheiron, half man and half horse, who is designated as the teacher of many of the Homeric heroes, is mentioned as the discoverer of the medicinal virtues of plants, just as Palamedes is called the inventor of letters and Orpheus the inventor of instrumental music. Similarly Genesis makes Jubal the father of such as handle the harp and the organ, and Tubalcain an instructor of those who forge cutting instruments of brass and iron. As every art must have had a beginning, it is in accordance with the naïve manner of thought to attribute it to some person. Men had not yet learned that the handicrafts are the result of an evolutionary process, and that they reached the highest perfection by the contributions of many. As long as the specific influence of natural causes and unnatural conditions in the genesis of disease was little known or even suspected, it is no wonder that men usually attributed both personal and endemic diseases to the special visitation of the gods. The same god might be a healer at one time and the bringer of disease and calamity at another. Under the strict monotheism of the Jews Job in-quires whether we shall not receive evil at the hands of God as well as good. David likewise declares that the arrows of the Lord stick fast in him and His hand hath pressed him sore. With all our superior knowledge it is not uncommon for people to speak of a dispensation of Providence when a little reflection would convince them that the supposed dispensation is due to ignorance, to unsanitary conditions, or to unhygienic practices. Everybody who reflects knows that fully four fifths of the diseases and misfortunes that come upon men are owing to preventible causes. Although misfortunes and accidents are frequently the result of conditions over which the unfortunate inrividuals have no control owing to the exigencies of our civilization, the responsibility is human and not providential. Some person or persons could have prevented them. The other fifth is brought about by those mysterious forces which, while in a measure understood, can neither be foreseen nor controlled.

Although Hippocrates shows in numerous pas-

sages that he is very much of a rationalist he often realizes that the skill of the best physician is baffled. In one of the passages of his works that has cogent evidence for its genuineness he says: "Medicine inclines to do honor to the gods as concerning symptoms of sickness, and doctors give way before them, since medical lore has no superabundance of power." We find a similar reliance upon the gods expressed by Socrates when he advises his friends to depend upon the human intellect for everything that lies within its scope, but to call upon the gods when they have to deal with matters that lie beyond this

We have no evidence that the Greeks anterior to the time of Aristotle dissected cadavers. However, their well known aversion to the mutilation of the human body even after death would render it advisable for those who had performed dissections to say little about it. Most people still share this aversion. After the doctrine of bodily resurrection had become an article of the popular creed, dissection was absolutely forbidden. The fate of Vesalius is well known. On the other hand, we have reason to believe that not only human corpses were dissected in Alexandria under the first Ptolemies, but that malefactors were sometimes subjected to treatment that differed little from vivisection. There was, however, no lack of opportunities for the study of the human skeleton on the numerous battle fields. When Greeks fought against Greeks the dead of the defeated army were usually given up under a truce. With the barbarians such generally was not the case. There is no room for doubt that on many a battle ground skeletons might be seen long after the combat had occurred. The phrase "gave their bodies to the dogs and birds of prey" that occurs in the first lines of the Iliad and oftener can hardly have been a mere figure of speech. Herodotus reports that after one of the engagements in northern Greece between his countrymen and the Persians "on the one side, a thousand men were seen lying about the field, on the other four thousand crowded together in one spot. He also relates that at the battle of the Thermopylæ "a still greater number were trampled to death by their own soldiers; no one heeded the dying.

There is one phase of ancient surgery that strikes tts as remarkable by its omission. Not only is there virtually nothing said about the sanitary affairs of armies; the care of the wounded is perfunctorily referred to. Although the ancient states were almost constantly at war they appear to have taken no systematic care of their soldiers when in the field. While Thucydides devoted an entire volume to a war between Greek states that occupied their entire energies on land and sea for a number of years toward the close of the fifth century B. C., he ignores this matter entirely. Neither does any writer on the history of early Rome make mention of surgeons with the army. In the time of Xenophon the noncombatants among the Spartan troops, but with equal rank with the regular soldiers, are soothsayers, physicians, and flutists. The same writer, in his account of the retreat of the ten thousand, tells us that at one time "they came into villages and appointed eight physicians; for there were many wounded." It is plain from this passage that these unfortunates had no regular care when on the march, but that the "physicians" were merely a sort of caretakers selected a good deal at random. That the nobility, especially the king of Persia, had their private physicians with them when in the field, is evident not only from the story of Democedes, but also from the statement of Xenophon that after Artaxerxes had been wounded in the head at the battle of Cunaxa, his Greek physician, Ktesias, healed him. In another work the same writer informs us that after a battle Cyrus sent the wounded into the city of Gadata "in order that they might be healed." That this was a regular custom is made probable by the passage in Herodotus describing the retreat of Xerxes from Greece.

To what extent Alexandria was provided with hospitals and opportunities for clinical practice we have no means of knowing. Our ignorance is due to the destruction of its libraries. It is, however, a safe inference from the silence of ancient records that hospitals were rare. We know from the testimony of the Bible that begging was very common, and that many insane and crippled were at large. The fact that certain temples were under the special patronage of the gods of healing and that they were much patronized by the sick renders it probable that special buildings for invalids were rare all over the ancient world. The diseased and impotent repaired to the temples to be healed. On the sites of these many votive offerings have been brought to light by the pick and spade of the excavator. Usually some local conditions, most frequently a medicinal spring, gave celebrity to a shrine. We have a typical instance recorded in the fifth chapter of St. John's Gospel. "There is at Jerusalem, near the sheepgate, a bath with five colonnades round it. . . . In these colonnades numbers of invalids were lying-some blind, some lame, and others crippled. One man was there who had been an invalid for thirty-eight years." That he had been placed in that spot by his relatives, who had then gone away and left him to his fate, is evident from the man's words: "I have no one to put me into the bath, when there is a movement of the water, and while I am getting to it, some one else steps down before me.

Owing to this lack of hospitals, except so far as a temple here and there provided a partial substitute, ancient medicine was largely personal. When a man had acquired a reputation by that peculiar insight, that power of mental divination which still distinguishes one physician from another of equal intellectual attainments, he began to attract pupils. He was attended by them to the bedside of his patients, where a diagnosis was made. The historians of the Alexandrian period, especially Susemill, who is chiefly indebted to Celsus and Galen for his information, have collected a large number of names of ancient physicians who are reputed to have made important discoveries and to have been the founders of schools; but when we sum up the errors and false views to which they gave currency we become painfully aware of their shortcomings.

While the study of ancient Greek medicine is both interesting and instructive, it cannot be said to be profitable. Furthermore, although there is no

doubt that its superiority is due to the fact that most practitioners were, in a sense, philosophers, there is just as little doubt that the penchant for system eventually prevented its further advance. Too much stress was laid on preconceived theories and not enough on careful observation. On the other hand, we need to be reminded occasionally that incredulity is not necessarily wisdom. That it is sometimes the very opposite is proved by the disdain with which Harvey's theory of the circulation of the blood was first received by nearly all contemporary physicians. When the bacterial origin of disease was first broached, as also when mosquitoes were first designated as the cause of yellow fever, both suggestions were for a number of years ignored. Outside of medicine similar cases are almost numberless. Again, when we remember how much the healing art is dependent upon instruments of precision, especially the microscope, we need not wonder that the ancients without these got no further than they did. For more than a millennium and a half it did not advance beyond the stage to which they had brought it. Indeed, our astonishment at the insight and the skill, no less than our admiration for the kindliness and humaneness of Greek physicians, grows in proportion as our knowledge of the entire subject increases. When considering the problems presented by the study of ancient medicine, especially after we have learned how inferior it was in many respects to the most advanced science of the present day, we are prompted to ask, what was the condition of public health? Apparently very little was done in the way of municipal sanitation, except that some cities were well supplied with water. Soap was unknown to the classical age both in Greece and Rome. Pliny mentions a compound which he calls sapo made by the Gauls and Germans, and the ingredients that entered into it. He also informs us that it was more used by the men among the latter than by the wo-It appears, however, to have been a pomade for the hair rather than a soap. Whether the term is Celtic or Teutonic we do not positively know; probably the latter. That the word was later borrowed by the Greeks from the Romans appears certain from the name sapon still in common use among them. The name eventually was adopted by most of the people of Europe, the Turks calling this article so much in demand in our day sabun and the Finns saippio. In its stead the ancient Greeks used flesh scrapers. These were so highly esteemed that they were sometimes made of gold and given as prizes in athletic contests. Herein we see how men's ideas of the fitness of things change with the people and the age. Nowadays one would hardly commend himself to a friend or an acquaintance by the gift of a cake of soap or a comb.

This can, however, not be said of Athens. The mortality does not seem to have been much greater than it is in our own day. Five hundred years B. C. the average of human life was reckoned at about thirty-three years. We are often astonished at the enormous population assigned to some countries. There were few large cities in the modern sense of the term; as the houses were seldom more than two stories in height the population cannot have been very dense. In Athens the reputable women sel-

dom went out of doors; the men spent most of their time in the open air. What effect occasional overcrowding produced may be seen from the description of the terrible plague in Athens near the end of the fifth century B. C., as given by Thucydides, when the surrounding population was driven into the capital by the exigencies of war. As the countries of which we know most were grouped around the Mediterranean Sea, where the climate is mild, outdoor life occasioned no discomfort, to say nothing of habit. In some parts of Italy whole families still live in caves. In Spanish cities the tourist who is out late at nights is surprised to find the streets littered with persons lying asleep; to the natives it is the most natural thing in the world. The population of China is evidence that filth is not incompatible with an exceptionally large number of in-habitants to the square mile, notwithstanding the prevalence of infanticide. The writers who have made the most careful study of the economic condition of France have reached the conclusion that the population of the country at the close of the middle ages was as great as it is now. It was, however, fearfully cut down by the Hundred Years' war and the plague. Yet during all this period there was no rational practice of medicine. Until quite recently most of the villages of continental Europe were without a resident physician. Such is still the case in many parts of the world that are reckoned civil-

While nobody doubts that medical practice fills an important want in modern civilization, there is no question that it is largely due to civilization that the want exists.

OBSTETRICAL PARALYSIS.

A Preliminary Report of Two Cases Treated by Nerve Dissociation.*

By Karl Osterhaus, M. D., Norfolk, Va.

Obstetrical paralysis, brachial birth palsy, is a condition affecting the upper extremity, caused by

some injury at birth.

Although this affection has been occasionally referred to in literature under various names (usually "compression paralysis") since 1768, it was not until 1872 that it was first recognized and described by Duchenne as a true laceration paralysis due to forcible delivery, though the actual nerve lesion was not understood by him. Until the last eight years very few cases of this disease have been reported. and even at the present time the literature on the subject is very limited. A few articles have appeared on the ætiology and pathology of the lesion but the most exhaustive and interesting of any which have come under the writer's notice, and the only ones in his opinion which cover the entire field, are the papers of Clark, Taylor, and Prout in 1905, and Bullard in 1907. It is not the inteniton of the writer to try to add anything to what has already been so ably discussed in these articles concerning the ætiology, etc., of brachial birth palsy, but rather to make a preliminary report of two cases in which

'Read before the Medical Society of Virginia, in session at Richmond, Va., October 20 to 23, 49.98

he operated by a somewhat different method from that usually employed, a method which, so far as he knows, was first advocated by Babcock, of Philadelphia.

While brachial birth palsy has been variously attributed by the earlier writers to direct compression of the cords of the brachial plexus by forceps, axillary hooks, by backward displacement of the clavicle, and to a form of anterior poliomyelitis, later experiments go to prove conclusively that it is caused by excessive traction or tension on the nerve roots of the plexus. Anything tending to force the head and shoulders away from each other puts the nerves on the stretch, though how this force is produced is not always clear, the disability in rare instances following apparently normal labor. Usually, however, there is a history of prolonged or difficult labor in which forceps or some other form of traction has been used. A. S. Taylor has very plainly demonstrated by his experiments on the cadavers of young infants that it is almost impossible to compress the cords of the plexus between the clavicle and first rib, or the transverse processes of the first cervical vertebræ, unless, perhaps, there has been a fracture of the clavicle, and in this event the paralysis would be confined to the lower nerve roots. According to Stimson, however, the cases of fracture of the clavicle in adults in which symptoms of paralysis appeared at the time of the fracture were very few, and in most of these there was paralysis of the suprascapular nerve which leaves the upper part of the junction of the fifth and sixth cervical nerves well above the clavicle, and this is certainly suggestive of laceration due to stretching. The production of obstetrical paralysis is favored by anything which tends to increase the resistance to the descent of the shoulders in vertex presentations, or of the after coming head in breech presentations, such as a small pelvis, inelasticity of the maternal soft parts, dry labor, or maternal exhaustion. Forced lowering of the shoulder girdle, which occurs when the tip of the shoulder catches at the brim of the pelvis or under the symphysis pubis, predisposes strongly to injury to the nerve roots, especially the upper ones. In the same way delivery of the resistant after coming head by making traction with the fingers hooked over the shoulders puts the cervical nerves on the stretch, and in such cases the danger of laceration is increased by direct pressure of the fingers on the already overstretched cords (A. S. Taylor). Incomplete rotation of the head, or rotation to the opposite side, together with inclination of the head away from the stretched nerves adds greatly to the strain, and traction made in this position is much more apt to cause laceration than when in line of the body. Asphyxia, by causing relaxation of the muscles protecting the plexus, may also be a predisposing factor in causing overstretching of the nerves.

The pathology of the lesion, as revealed post mortem or by operation, is the same as that of similar injuries to nerves elsewhere. The injury varies from a simple stretching of the nerve fibres to complete laceration of the plexus. As usually seen, however, it consists of a stretching of some of the fibres and a tearing or unravelling of others at different levels, the fifth and sixth cervical nerves be-

ing most often affected. The supporting connective tissue perineural sheath with its contained blocdvessels is the first to give way under excessive strain, causing hæmorrhage which infiltrates the nerve substance. Organization of the resulting blood clots, which occurs before regeneration of the nerve fibres begins, forms scattered bands of connective tissue around the nerve bundles, constricting them, and thus effectually preventing their regeneration. Naturally the greater the hæmorrhage the greater is the resulting cicatrix, and the more far reaching the extent of the paralysis. The injury to the nerves is still further complicated in many cases by laceration of the deep cervical fascia covering the plexus, and this may be found adherent to the cords of the plexus. In nerve lesions due to overstretching the peripheral fibres are always more injured than the central ones.

The three varieties of obstetrical paralysis, depending on the site and extent of the lesion, are upper arm paralysis, lower arm paralysis, and total arm paralysis. The first named is the type usually met with, though paralysis of the whole extremity is not uncommon. In upper arm paralysis, of which both the writer's cases are typical, the muscles always involved are the deltoid, biceps, brachialis anticus, and supinator longus, and usually associated with these the supraspinatus and infraspinatus, serratus magnus, supinator brevis, and teres minor. The clinical picture presented in a case of upper arm birth palsy shows the arm hanging loosely from the shoulder, the whole extremity being rotated inward. There is marked pronation of the hand, and the elbow is usually slightly flexed and cannot be fully extended on account of contractures at the joint. In more severe cases of long standing the pectoralis major is strongly contracted, and there may be flexion deformity at the wrist. Backward dislocation of the humerus sometimes occurs owing to relaxation of the muscles around the shoulder joint and to the contraction of the pectoralis major. In one of the writer's cases this subluxation takes place every night during sleep, and is reduced by the patient every morning as a preliminary step to making her toilet. The voluntary movements of the arm are very much restricted, abduction, supination, and outward rotation being practically impossible. In recent cases a severe neuritis is sometimes present, and movement or handling of the extremity causes much pain and discomfort. In cases of long standing there is marked atrophy and lack of development of the limb, the normal bulge of the shoulder is flattened, and the acromion may be prominently seen. The handgrip in the true upper arm type is usually very slightly affected, and the hand may be used in a nearly normal manner. Sensation seems to be unaffected.

A diagnosis may be made without difficulty from the characteristic position of the extremity, together with a history of a difficult or prolonged labor in which traction in some form has been used, and which is closely followed by paralytic symptoms. Electrical tests of the muscles and the atrophy and dwarfing of the extremity will confirm the diagnosis, if any doubt exists. At times, however, it is almost impossible to determine all of the nerves involved or the extent of the lesion, though electri-

cal stimulation at Erb's point (two centimetres from the outer border of the sternocleidomastoid and the same distance above the clavicle) will cause contractions of all the paralyzed muscles supplied through the fifth and sixth cervical nerves. Sometimes deep palpation over Erb's point will reveal the thickened areas in the injured nerves, and may be of service in determining approximately the extent of involvement of the nerve trunks, but this is only possible in thin patients and cases of long standing.

The prognosis in brachial birth palsy may be said to be good in the upper arm cases in which operative measures are employed. Nerve surgery at the present time holds out a promise of at least partial return of function even when the paralysis is very extensive, and in many cases complete restoration of function may be hoped for, though only after a considerable lapse of time. It is certain that the nutrition and development of the arm will be materially improved by any operation on the nerves that will relieve the constriction or pressure of the fibres. Even in cases in which the whole extremity is involved much may be accomplished, though any great amount of usefulness of the limb is not to be expected. The prognosis is also affected to a great degree by the length of time which has elapsed since the onset of the paralysis, the younger the patient the better being the chances for recovery,

In the treatment of recent cases of obstetrical paralysis, as in infantile paralysis, it should be the aim of the surgeon to assist in restoring as far as possible the functions of the muscles only temporarily affected, and to prevent contractures of the sound muscles. To this end electricity, massage, baking, passive motions, and hot and cold douches should be systematically employed. It is hardly necessary to state that these therapeutic measures are not to be attempted in cases presenting an "active" neuritis, as they would only cause unnecessary suffering and tend to aggravate the disease. In the latter cases the extremity should be immobilized in a splint or plaster of Paris cast in such a position as to prevent contractures, and this splint should not be removed until all acute symptoms have subsided.

The length of time which should elapse before an operation is attempted is a question that admits of much discussion, Kennedy and others believing that three months is sufficiently long to wait after paralysis has been established. On the other hand, Clark and Taylor think that at least eight months should be given the temporarily affected muscles to regain their power, and that even a year is not too long. In the opinion of the writer to wait at least a year or two years after the onset of the paralysis would be entirely proper, as not only would the operative field be enlarged but the danger of shock to the child would be greatly lessened.

The technique of the operation commonly employed for the relief of this condition has been fully described by Taylor in his excellent article, and the writer will only repeat his description here. An incision is made along the posterior border of the sternocleidomastoid muscle extending obliquely downward and outward from the junction of its lower and middle thirds to the clavicle at the junction of its outer and middle thirds. The platysma

and deep fascia are divided, exposing the omohyoid muscle and suprascapular vessels. These are retracted downward or divided between double ligatures, as are also the transversus colli vessels, which are found just below the middle of the wound. The incision is carried through the layer of fat covering the deep cervical fascia, under which lies the brachial plexus. This fascia which is usually thickened and sometimes adherent to the plexus, is divided and cleared away from the nerve roots exposing them freely. The injured nerves are usually more thickened than the healthy nerves, and palpation will reveal indurated areas in the substance of the nerve, in most cases at the junction of the fifth and sixth cervicals. These masses of scar tissue should then be excised with a sharp scalpel or tenotome. The use of scissors in cutting the nerve and handling it with forceps are to be condemned, as in this way the nerve fibres are bruised too extensively and their regeneration is interfered with. After excision of the cicatricial tissue the nerve ends are brought together by lateral sutures of fine silk, the sutures being passed through the nerve sheaths only, to avoid injury to the healthy fibres. The writer prefers for this work fine carbolized catgut or some other form of absorbable animal suture. While the sutures are being tied the neck and shoulder are approximated as much as possible to prevent any tension on the nerve union. Cargile membrane is then wrapped about the anastomosis to prevent ingrowth of connective tissue. The omohyoid is sutured with catgut, and the platysma and skin with silk or a subcuticular silver wire stitch. A light sterile dressing is applied, then a plaster splint to keep the head and shoulder appromixated. This splint must be continued for three weeks or a month to avoid any strain on the anastomosis until firm union has taken place.

If necessary in the more extensive lesions the skin incision may be carried down between the pectoralic major and the deltoid, which are then separated. The clavicle is divided with a Gigli saw, and the subclavius muscle also. These structures are then retracted exposing the entire brachial plexus. After the anastomosis has been completed the clavicle and muscles are reunited with chromic gut.

The method adopted by the writer in his cases was first suggested to him by the results following its application to a case of infantile paralysis, in which he had previously made an anastomosis between the internal and external popliteal nerves. The improvement in this case, while marked, was rather slower than in other cases in which the same operation had been performed, and led him to suspect an overgrowth of connective tissue at the site of the wound, which on investigation proved to be the case. Not wishing to run any further risks of cutting off the nerve supply by dissecting out the scar tissue, which evidently involved only part of the diameter of the nerve trunks, it occurred to the writer that possibly an application of the principle of bridging nerve gaps with a foreign material might be of service in this case, by allowing the scar tissue to take the place of the catgut strands commonly employed. To this end the nerve junction was carefully lifted on two fingers, the nerve sheaths having been previously split up for a considerable distance above and below, and with a fine sharp tenotome the nerve fibres constricted by the cicatricial bands were thoroughly dissociated. Cargile membrane was then applied loosely and the wound closed. The return of function which followed was almost startling in its rapidity, and the question was raised in the mind of the writer whether such a procedure would not be good routine practice after all nerve anastomoses, in which restoration of function is much delayed by connective tissue formation.

The report of a series of cases by W. Wayne Babcock, of Philadelphia, in which nerve dissociation had been performed, and in which he advocated the latter procedure in the treatment of brachial birth palsy led the writer in November, 1907, to attempt it in two cases of upper arm paralysis which he had under observation at that time, the preliminary reports of which are given herewith. As only a little over eight months have passed since these operations were performed the final results are still in doubt, but so far the improvement has been most encouraging.

CASE I.—S. H., aged sixteen years; female; white; strong, healthy girl, with typical left upper arm paralysis of moderate degree. History of vertex presentation, eighteen hours' labor, forceps used. Disability not noticed un, ill nearly two months after birth. No history of a neuritis. Function seemed to improve for about a year, but since then there had been no improvement. There were contractures at the elbow joint, resulting in a mild degree of flexion, and the pectoralis major was markedly contracted. The arm could not be voluntarily abducted except to a very slight extent, and outward rotation and supination were almost entirely absent. Examination showed involvement of the firth and sixth cervicals, but no induration or thickening could be made out on palpation, owing to fat. Marked atrophy of arm and shoulder, left arm being two inches shorter than right.

Operation on November 8, 1907. Under ether anæsthesia the plexus was exposed by the usual incision above the clavicle. The deep cervical fascia was found to be thickened and somewhat adherent to the plexus. Palpation showed several small indurated masses at the junction of the fifth and sixth cervical nerves, one mass extending a little distance into the fitth nerve above the junction. The deep cervical fascia was cleared away freely so as to expose the nerves, and the nerve sheaths were incised longitudinally from well above the junction to below it. The nerve junction and roots were then lifted clear of the sheaths on small padded grooved directors, and the fibres were freely dissociated, the dissociation being carried into the nerves well above and below. The suprascapular nerve was treated in the same manner. The nerves were then loosely wrapped in Cargile membrane, the wound closed in layers, and a plaster cast applied to approximate the head and shoulder. There was very little loss of blood, and the patient reacted well. Time of operation, one and a quarter hours.

The skin wound healed by first intention, and one month after operation the cast was removed and a strict course of electricity, massage, baking, and passive movements was instituted. The patient was instructed to use her arm as much as possible and attempt to exercise the paralyzed museles. Some slight improvement in function was noted about four months after operation and this steadily progressed. At the present time the patient can abduct the arm nearly to a right angle to the body, and flexion, outward rotation, and supination are markedly better.

The atrophy and dwarfing of the extremity, which were considerable, appear about the same. It is worthy of note that the patient can now feed herself with her left hand, which before was impossible.

that the patient can now feed nerself with her left hand, which before was impossible.

CASE II.—C. D., female, white; aged four years; large, well developed child, in perfect physical condition, except for mild degree of obstetrical paralysis of left upper arm. History of dry, difficult labor of about ten hours' duration, in which forceps was used. Vertex presentation. Paralysis

age palliative treatment was begun and persisted in for about six months, during which time there was some improvement. The child presented a typical clinical picture of the upper arm type of brachial birth palsy, the arm hanging close to the body with the elbow slightly flexed, the hand pronated, and the entire extremity rotated inward. Voluntary movements were much restricted. On account of fat, palpation over Erb's point failed to disclose any thickening or induration. Atrophy of the arm and shoulder was noticeable, and the left arm was somewhat shorter than the right. The hand could be raised a little above the waist line with an effort, but could not be supinated. No outward rotation.

Operation on November 14, 1907. Under ether anæsthesia the usual incision was made above the clavicle and the plexus exposed. Deep cervical fascia was not markedly thickened. A small indurated area could be palpated at the upper outer part of the junction of the fifth and sixth cervical nerves, extending into the fifth nerve. The nerve sheaths were incised and the nerves raised on grooved directors, as in Case I, and freely dissociated, the process being carried up into the fifth and suprascapular nerves. Cargile membrane was applied, and the wound closed in layers, silver wire being used for the skin. A sterile dressing and plaster cast were then applied. Reaction was rapid and loss of blood slight. Time of operation, one hour.

ing and plaster cast were then applied. Reaction was rapid and loss of blood slight. Time of operation, one hour. The skin wound healed uneventfully, and the cast was removed at the end of a month. Six weeks after the operation the child had a severe attack of scarlet fever, from which convalescence was rather slow and tedious. Electricity and the other therapeutic measures had to be omitted for nearly three months following operation, except for perhaps ten days. In spite of this handicap some return of power was noted during convalescence, and this steadily improved. The electrical reactions of the paralyzed muscles were marked, and the child can now raise the hand to her mouth, and the arm to a level with her shoulder. The hand can be turned nearly half way over, and there is some power of outward rotation. All the movements, however, are weak and accompanied by decided effort, but this is to be expected.

In conclusion the writer wishes to express his conviction that this method will be found of distinct advantage in many cases of brachial birth palsy in which extensive resection of the nerves would be of doubtful benefit. In both of his cases the benefit derived has been decided and rapid, in spite of the fact that one case was of sixteen years standing, and the chances of their ultimate recovery seem good. Undoubtedly much less harm is apt to be done by separating the fibres than by excision of the cicatricial masses. Dissociation by relieving the pressure and constriction of the nerve fibres open up new pathways for their regeneration, and as far as may be judged from the two cases cited here the restoration of function seems to be brought about much more rapidly than in cases in which resection has been performed. The theory that the regenerating axis cylinders will use the strands of degenerated nerve fibres and scar tissue as bridges on which to extend themselves, similarly to vines on wire, certainly seems sound, and it only remains to prove or disprove this theory in actual practice. The writer would heartily urge a thorough trial of this method in all cases of nerve injury, but particularly in the distressing condition which is the subject of this paper, as being a procedure in which the chances of doing much good are so great, and of doing harm so small. It is a source of much regret to the writer that he is unable to accompany this article with photographs of his cases, but owing to the modesty of the older girl, and his inability to reach the younger child, he was forced to do without, though recognizing that the value of this report is greatly lessened without them

The later status of these two cases will form the basis of a subsequent report.

CAUSE OF PREMATURE SEPARATION OF THE PLACENTA.

BY SAMUEL ROBBINOVITZ, M. D., Brooklyn, N. Y.

Owing to the failure of Dr. Lionel Rosenberg, of Brooklyn, to clearly understand my article contributed to the New York Medical Journal on the subject of Cause of Premature Separation of the Placenta, I find it essential for the purpose of defending myself against an unjust and false accusation by him to make the following statements and

recapitulation respecting this subject: The doctor entered a very bold statement in the columns of the New York Medical Journal, June 20, 1908, whereby he endeavors to imply that premature separation of the placenta cannot take place unless there is some predisposing cause, and that gonorrhaal metritis is, in his estimation and experience, usually the predisposing cause, and, hence, he does not agree with my idea as put forth in my contribution to the New York Medical Journal of March 14, 1908, where I asserted that the most frequent cause out of all causes enumerated in the standard works on obstetrics, in my opinion, is traumatism, in the form of either direct or indirect violence, as I found by my own personal experience and careful investigation. Dr. Rosenberg, furthermore, accuses me of publishing Professor Jewett's ideas and alleging that the same were my

In my opinion, it is only after a close study and thorough comprehension of any article on any subject that one could venture upon criticism, and, inasmuch as Dr. Rosenberg's view upon the same offered neither forethought nor even slight consideration of the subject in question, I have no hesitation in saying that he ought rather to hesitate to contradict anything which may not have been obvious to him.

If the medical readers of the New York Medical Journal will be kind enough to turn to page 501 of the Journal, March 14, 1908, issue, they will readily see that by discussing there the subject as I did I usurp no originality about the cause of premature separation of the placenta, but what really is my original idea is the fact that the most frequent of all causes mentioned in textbooks is traumatism. I assert that the latter idea is my original one, for the reason that I never heard of this idea being mentioned nor have I seen it published anywhere, but it simply is based upon personal examination and practice in these matters. I wish to defend myself thoroughly against this unjust accusation and at the same time also express my contradictions to the ideas of Dr. Rosenberg, represented in the article he recently contributed: I, I have in my possession Professor Jewett's second edition, Essentials of Obstetrics, on page 300, of which he enumerates a certain number of causes, and among them he mentions "external violence, as blows or falls," but he never states definitely that any particular one of them is the most frequent of all he mentions. 2, Wherefrom and by what authority did the doctor determine that no separation of the placenta could take place prematurely unless there was some predisposing caurse? I never saw, on referring to standard works on obstetrics, it mentioned by any author, including Dr. Jewett, that it is absolutely necessary that a predisposing cause be at the bottom of such an accident. Then, again, on the other hand, if there is any author that maintains such an idea, it is, after all, not the doctor's original view. To support my contradiction I may state that the majority of my patients who had accidental hæmorrhage, i. e. premature placental separation, were perfectly well women, having had no leucorrhoeal discharge or any other cardinal symptoms of metritis, had no physical defects of any kind, neither anæmia nor ill health, and certainly no gonorrhæal metritis, which the doctor stated they must have in order that such a condition might occur. In the majority of such cases I found that the untimely separation of the afterbirth was purely due to the act of traumatism, either by direct or indirect violence, as I illustrated in my article. 3, According to the doctor's arguments, which I beg to quote: "Upon repeated examination of Mrs. M. M. I found that she had gonorrhœal inflammation in its severest form, and so I came to the conclusion that premature separation of the placenta was due to metritis set up by the gonorrheal infection, which acted as a predisposing cause, and the manipulation of the midwife acted as an exciting cause." Consequently every woman having premature placental separation must necessarily have had a gonorrheal infection, as will be shown by and as can be elicited from his statement I quoted. He certainly takes great liberty when he makes such a bold statement, and if this article should ever be destined to be read among the average lay people, I think the doctor would have a hard task in defending himself. It can readily be observed how absurd and ridiculous such an argument on his part is, especially when (as can be learned from his quotation) he bases his conclusion on one single case of the kind which he had where premature separation took place on account of the infection with the gonococcus. It would be an extremely unfortunate state of affairs if all authorities on obstetrics were to give such an idea as their conclusion, since, no matter how decent or virtuous a woman might be, she would be considered the opposite if her placenta were to separate itself too early, and we should be constantly suspicious and troubled even about our own mothers, sisters, and wives as to their morality if they should happen to meet with any accident of traumatism during the last month or two of pregnancy and this accident happen to occur to them.

71A SUMNER AVENUE.

Our Readers' Discussions.

A SERIES OF PRIZE ESSAYS.

Questions for discussion in this department are announced at frequent intervals. So far as they have been decided upon, the further questions are as follows. LXXIX.-How do you treat sick headache? (Closed

October 15, 1908.) LXXX.—How do you treat asphyxia neonatorum? (Answers due not later than November 16, 1908.)

LXXXI.—How do you treat chronic eczema? (Answers

due not later than December 15, 1908.)

Whoever answers one of these questions in the manner most satisfactory to the editors and their advisers will be attached to literary style, but the award will be based solely on the value of the substance of the answer. It is requested but not required) that the answers be short; if practicable, no one answer to contain more than six hundred words.

All persons will be entitled to compete for the prize, whether subscribers or not. This prize will not be awarded to any one person more than once within one year. Every answer must be accompanied by the writer's full name and address, both of which we must be at liberty to publish. All papers contributed become the property of the JOURNAL.

OUR READERS ARE ASKED TO SUGGEST TOPICS FOR DISCUSSION.

The prize of \$25 for the best essay submitted in answer to question LXXVIII has been awarded to Dr. Charles
Floyd Burrows, of Syracuse, N. Y., whose article appeared

on page 842.

PRIZE QUESTION LXXVIII.

THE TREATMENT OF ACUTE CORYZA.

(Continued from page 844.)

Dr. Arthur H. Paine, of Geneva, N. Y., remarks:

The treatment of acute coryza should aim to assist the natural forces of the human economy in combatting an acute general infection with localized symptoms. The important points to be considered are: I, Rest; 2, (a) opening of all channels of elimination and (b) equalizing circulation; and 3, fortifying the system to form antitoxine and overcome in-

I. Rest is secured by absolute quiet in bed and the administration of a suitable dose of Dover's powder at bedtime.

2. (a) Channels of elimination are opened and stimulated by the administration of castor oil, which will clean out the alimentary canal; Dover's powder and warm covering will produce diaphoresis, and sweet spirit of nitre, together with plenty of water ingested, will increase renal activity.

(b) Relief of the congestion of nasal mucosa can be afforded by a hot mustard footbath and maintained by administration of a mixture of aconite, belladonna, and sweet spirit of nitre, which will inci-

dentally reduce fever.

3. The fortification of the system if accomplished by the enforced rest and judicious feeding with highly nutritious but readily assimilable food, at fre-

Therefore, the treatment of an attack of acute corvza seen at or near the onset would resolve itself

into the following:

One half ounce of castor oil as first measure, followed by a hot mustard footbath and immediate retirement to bed with warm covering. Give a mix-

ture of aconite, belladonna, and sweet spirit of nitre, grading the dosage to fit the individual every hour or two while awake. At bedtime, give Dover's powder, 5 to 10 grains. Encourage cold water to be taken freely, but withhold food until the laxative has operated and the bowels are quiet, then give raw eggs and milk every two hours.

If these measures are carried out faithfully, the attack will terminate in a very short time and the stage of purulent nasal discharge will be aborted. Local treatment will avail no permanent good nor tend to cure condition, though sometimes it seems advisable to use some alkaline spray, as Dobell's solution, followed by a spray of

B Camphor,gr. v; Menthol,gr. viii;

When a case is encountered comparatively late in its course and the nasal mucosa is boggy and secretion well established, this local treatment will be most useful. The general treatment will then consist in forced feeding and tonics, such as quinine, gr. i to ij three times daily.

Dr. Meyer A. Rabinowitz, of Brooklyn, N. Y., observes:

The successful treatment of acute corvza must be based on the ætiological, pathological, and clinical indications present. The predisposing cause in almost all cases is a condition of the system below par; the exciting causes are numerous and vary with each individual case, as undue exposure to damp weather, sudden chill, irritating vapor, or overheated and overcrowded atmosphere. The onset is marked with congestion, dryness, and swelling of the Schneiderian membrane, interfering with proper drainage of the nasal sinuses, and producing headache and feeling of nasal stuffiness. This later gives place to vascular relaxation attended with nasal discharge-first mucus, then mucopus. Once the disease is well established it pursues a subacute course tending to recovery, but very liable to recurrences unless the ætiological factors be removed. It therefore follows: During the attack, limit the disease at onset, and failing in this, relieve distressing symptoms; after the attack, remove local and general predisposing causes, and warn against exciting

Treatment at onset, i. e., in first twenty-four hours, should be abortive. Nasal congestion must be overcome by cutaneous dilatation, catharsis, and rest. A hot mustard foot or sitzbath taken at home, followed by a hot drink of lemonade in bed, with plenty of blankets about to keep up perspiration, is of unquestionable value, assisted by one powder containing 10 to 15 grains of Dover's powder and 5 grains of quinine sulphate. A serial dose of calomel, 1/10 grain every 10 minutes for ten doses, should be given before bedtime, and a brisk saline ordered the next morning. Locally, a four per cent. aqueous solution of cocaine applied by the physician only, where there is danger of habit; or applications of a I in 10,000 adrenalin chloride solution in normal saline every four hours by means of swab or nasal dropper will constrict the arterioles, shrink up the mucous membrane, and assist drainage. Should

headache and discomfort still be severe after following out the above, 5 grains of acetphenetidin repeated once or twice, as needed, will be sufficient in most cases.

When the disease is well established and there is profuse nasal discharge, abortive treatment will be useless. Local cleansing and soothing applications, nutritious full diet, moderate catharsis, and internal tonics are now indicated. Avoid too vigorous spraying for fear of carrying infection up the Eustachian tube or nasal sinuses. Gentle douching every three hours with tepid Dobell's solution or normal saline, followed by spraying with following solution:

Menthol,

This will prove efficacious. The patient should not go out into the open air for at least one half hour after, to avoid aggravating the local conditions.

Watch for and treat complicating otitis media or sinusitis. Avoid recurrences by raising economy above par and by removing all local predisposing causes in nose and pharynx—as hypertrophied turbinates, polyps, spurs, and adenoids.

Dr. W. Warner Watkins, of Phanix, Arizona, states:

The treatment of an acute coryza, or a "head cold," is a refinement of therapeutics which it behooves the physician to keep uppermost in his mind. First, from the standpoint of the physician himself, because it can be and should be aborted in order to prevent a catarrhal rhinitis, rhinopharyngitis, or graver sequelæ in the deeper respiratory tract resulting; and, second, because appearing to the patient, as it does, to be an affair of small consequence aside from the discomfort and inconvenience it causes, he wishes and expects to have the coryza promptly relieved. So the treatment of this ubiquitous ailment which is viewed with too little apprehension by the majority of our patients is very important, not so much on account of the rhinitis per se, but because of the segulæ which may result from a neglected inflammation of the nasal mucous membrane. And here, as with the treatment of any pathological condition, we must understand the structure of the tissues involved and the changes which occur in an infection of them in order to apply intelligently our curative agencies.

The nidus of infection in an acute coryza is the mucous membrane of the respiratory portion of the nasal fossa which includes all of the cavity except the upper and central portion of the sæptum and the superior turbinate, over which areas the olfactory nerve is distributed. The membrane is adherent to the perichondrium and is continuous with the conjunctiva through the nasal duct, with the tympanum through the Eustachian tube, and with all the sinuses communicating with the nasal fossa; over the turbinates and sæptum the membrane is very thick and vascular, but elsewhere it is pale and thin; the epithelium is of the columnar ciliated variety interspersed with mucin cells; in the basement membrane there are both serous and mucous glands opening by their ducts on the surface. The vascular supply is exceedingly rich, the veins forming cavernous tissue beneath the membrane over the

turbinates.

The essential pathology of an acute coryza is an intense congestion and turgescence of the mucous membrane of the respiratory portion of the nasal fossa, to which change its structure makes it easily susceptible.

The symptoms of occlusion are quickly produced by swelling within so small a space, and anosmia, conjunctival congestion, headache, impaired respiration, are the first symptoms; these are soon followed by a profuse secretion which is first serous and later mucus. The constitutional symptoms of any infection are present to a more or less degree—fever, loss of appetite, malaise, etc.

Treatment.—With these conditions to combat the indications for treatment are:

First-To relieve the congestion and to prevent or abort the stage of profuse secretion. This is done by a free catharsis, by counterirritation to the feet and legs, and by dilatation of the cutaneous capillaries, and the induction of a free diaphoresis. The patient should be confined to the house for two. three, or more days, if possible. If this is not feasible-and in many cases it is not-then let the patient take during the day atropine, 1/300 gr., every half hour until the throat and nose are dry. This will usually effectively check the nasal secretions. At night for catharsis. give calomel, gr. iii, with a brisk saline the following morning. For counterirritation and hyperæmia of the feet and legs and consequent vascular depletion of the head, have the patient take a hot mustard foot bath at bedtime, and at the same time take a full dose of spirit of nitre in a glass of hot water, sleeping under sufficient cover during the night to induce a free perspiration; the nitre is not only indicated for itself but is needed to offset the effect of the atropine on diaphoresis.

Second—To reduce the temperature, cleanse the affected area and restore the tone of the tissues and bloodvessels. Give aconite for its physiological effect on the bloodvessels; this reduces the temperature, dilates the cutaneous vessels, and relieves the local congestion in the nose. It may be given during the day with the atropine, but preferably in the evening.

Keep the affected area clean by a spray of warm normal saline solution or a weak alkaline wash applied two or three times daily. If the tissues do not return promptly to their normal tone and condition, aid the removal of the inflammatory products by some tissue alterative, such as arsenic and iodides.

Prophylaxis.—This is placed in the conclusion because it is where it naturally falls in our treatment, inasmuch as it covers the instructions to the patient as to how he may avoid contracting further colds—a matter about which many of them anxiously inquire. The writer was once given three rules for avoiding "catching cold," as follows:

- (1) Bathe the neck and the upper portion of the breast with cold water the first thing on arising in the morning.
- (2) Keep the upper part of the chest and the "shins" protected from chilling, as the chilling of these two particular regions of the body seems to induce a stagnation of blood in other tissues and organs, the nasal mucous membrane among them.

(3) Sleep always with a free circulation of air through the room, using sufficient cover for warmth. "Observe these rules and you will not contract colds," you may tell your patient.

Dr. William F. Barclay, of Pittsburgh, says:

For more than twenty years I have treated the disease in practically a routine method and it has been successful; I have no good reason to change the treatment. I direct fifteen drops of tincture of nux vomica every three hours in water. I order the tincture to be taken in one half a glassful of cold water, as it is more efficacious when well diluted. The dose recommended seems quite large, but experience has convinced me that the larger the quantity of the medicine taken the better the result from its use. The dose for children should be according to the age of the child. I have not observed any unpleasant effects from the use of nux vomica. In addition a small dose of calomel compounded with milk sugar, two to ten in proportion of the compound, acts well and never fails to benefit the patient. The cathartic should be taken before retiring to bed. This treatment is safe and satisfactory during the time of the acute attack and acts as a tonic during convalescence. When the acute stage is past the medicine should be taken three times daily. nostrils should be sprayed with a solution of adrenalin chloride in a saturated solution of boracic acid. with great advantage and with much comfort to the patient. Patients that I care for and treat when they are ill with acute coryza do not consult me, but resort to the treatment of their own accord. I would remark that the tincture of nux vomica should be prepared fresh from a reliable solid extract, as that made from the fluid extract is practically inert.

Dr. William Lynn Wilson, of St. Joseph, Michigan, writes:

Acute coryza is an inflammation of the nasal mucous membrane, and may be caused by I, exposure to cold or draughts, especially when overheated; 2, inhalation of mechanical or chemical irritants; 3, the toxic products of certain infectious diseases, as measles, scarlet fever, and influenza; 4, nervous conditions, as vasomotor coryza. A predisposition to this affection is also furnished by a number of local conditions, as the presence of adenoids, polypi, and deviated septum; and a certain number of people who possess an unstable vasomotor nervous system are especially prone to take cold on the slightest exposure.

The symptoms are both general and local, the general symptoms being lassitude, chilliness, aching of the muscles, and feverishness. Locally, there is at first a feeling of stuffiness and irritation, accompanied by snezing, and more or less occlusion of one or both nostrils, and followed by a profuse secretion, at first serous, afterwards mucous or muco-

purulent.

The treatment may be divided into prophylactic, abortice, and symptomatic. The prophylactic measures are avoidance of colds or draughts when heated or per paring, keeping out of the presence of dust and unitating gases or vapors, and the wearing of clothing suited to the atmospheric conditions. As a general rule, light wool, or silk and wool under-

clothing is to be preferred. The feet especially should be kept dry and warm. The house should be well ventilated and aired, and the temperature kept as nearly even as possible, and moderate in degree, as overheated, badly ventilated houses are responsible for a large number of cases of coryza. Sæptal deformities should be corrected, spurs, adenoids, and polypi removed, enlarged turbinates cauterized or removed; and the patient's vasomotor reaction should be educated by cold baths, exercise, and massage. Deep breathing exercises, followed by a cold plunge, or sponge bath, are excellent measures if carried out every morning.

Abortive treatment, to be effective, should be begun early, that is, within a few hours from the onset of the disease. A hot mustard foot bath, a prompt acting cathartic, as the effervescent solution of magnesium citrate, followed by a hot drink, to which may be added a half to one teaspoonful of sweet spirit of nitre, will in a certain number of cases be effective in breaking up an attack of coryza. In a larger number of cases, while it does not actually abort, it relieves the severity of the symptoms and shortens the course of the malady. In some cases the time honored Dover's powder may be given at the same time as the hot drink. In rheumatic subjects a dose of sodium salicylate, 15 grains, or aspirin, 15 grains, is effective. Occasionally a full dose of quinine, 10 to 15 grains, will prove abortive, and is always worthy of a trial.

After the first day these measures are of little or no avail, and the treatment must be mainly symptomatic. The general symptoms are best relieved by salol and acetpheneticlin, each 2½ grains, in a capsule, every two hours; or by the following:

 Fig. Tincture of aconite,
 .5ss;

 Potassium nitratte,
 .5ii;

 Sweet spirit of nitre,
 .5iii;

 Water,
 .9 s. ad. 5ii.

 M. S. A teaspoonful in water every 2 hours.

After the feverishness and aching have subsided a capsule of quinine gr. i, extract of belladonna gr. 1/12, and monobromated camphor 4 grains, given every two hours, will serve to further relieve the symptoms.

Locally a mild alkaline spray, containing sodium biborate and sodium bicarbonate, as Dobell's or Sciler's solution, should be used as a cleansing procedure. These solutions should be warmed to the body temperature before being used. Afterwards, a spray of a three per cent. solution of camphor menthol in liquid petrolatum should be employed; and in the milder cases nothing more is required. In cases where the tunnefaction is great and the nose almost completely occluded, a solution of cocaine, four per cent., and adrenalin chloride, 1 to 5,000, should be dropped into each nostril, or applied on absorbent cotton, and allowed to remain until the swelling is reduced, after which the three per cent. camphor menthol solution may be used.

This treatment can be used twice a day in the office, but I seldom give patients preparations containing cocaine to be used at home. For home use the warm alkaline spray, followed by an oily solution of adrenalin, or adrenalin ointment, is the most appropriate procedure. The menthol pocket inhalers that are on the market are also helpful. When the

swelling is not so great but there is a very profuse serous secretion, a powder composed of stearate of zinc and boric acid, equal parts, to which in some cases may be added a one half per cent. solution of cocaine, should be insufflated every three hours. usually dispense this powder myself, so that the patient need not know if it contains cocaine.

A powder composed of equal parts of pulverized acacia, bismuth subnitrate, and sodium bicarbonate, may also be used with advantage; and in some cases I use one made up of bismuth subnitrate, alum powder, and talc. Glycerin applied freely to the nose externally helps to relieve the stuffy feeling, and in children especially gives great relief. The ointment of rose water or the benzoinated oxide of zinc ointment should be applied to the nostrils externally to prevent irritation and excoriation of the skin. The patient should be told to resist as much as possible the desire to blow the nose, as frequent unproductive attempts increase the irritation and swelling.

The use of alcohol and tobacco should be pro-

hibited during an attack. (To be continued.)

Correspondence.

LETTER FROM LONDON

Women Admitted to the Royal Colleges.—The Harveian Oration.—The New Hospitals of Manchester.—The Children's Bill.

London, October 20, 1908.

The admission of women to the examinations for the diplomas of the Royal Colleges of Physicians and Surgeons is now an accomplished fact. At the quarterly meeting of the Council, on October 16th, under the chairmanship of Mr. Henry Morris, this subject came up for consideration on the motion of Mr. Clinton Dent. After considerable discussion the following resolutions were adopted:

a. That steps be forthwith taken to admit women to the examinations of the Conjoint Examining Board in England and to the examination for the diploma in public health.

b. That women be admitted to the examinations for the fellowship of the Royal College of Surgeons and to the examinations for the license in

dental surgery.

A committee was then appointed to prepare a formula for the necessary alterations in the bylaws. It will be remembered that recently a poll was taken by the Council of the fellows and members on this subject, and the result was a majority against the admission of women. The Council, however, is in no way bound to accept the decision of the members and fellows, and consequently Mr. Clinton Dent's motion was adopted. The diplomas now open to women are the M.R.C.S., L.R.C.P., and D.P.H. (granted in conjunction with the Royal College of Physicians), and the F.R.C.S. and L.D.S. The other diplomas of the Royal College of Physicians, the M.R.C.P. and the F.R.C.P., will probably also be open to women in a very short time. Thus ends a struggle which has lasted many years, several attempts having been previously made to secure the admission of women to the Royal Colleges without success. It is improbable that this will lead to any large influx of women into the medical profession. Most of the medical women are engaged in public health or school appointments; others are missionary medical officers. In general practice there has been very little demand for medical women, so that medical men in England are not very apprehensive of competition from that source. There are at present about 800 women on the British Medical Register.

The Harveian Oration was delivered yesterday by Dr. J. A. Ormerod at the Royal College of Physicians. The subject was Heredity and Disease. Dr. Ormerod first paid a tribute to Harvey. Ever since 1656, he said, these orations had, with few intervals, been delivered by a long line of distinguished physicians, and there could be little left to say of Harvey or his work. Harvey pondered on heredity, and the subject was therefore not outside the scope of the oration. First came the old question, Were acquired characters transmissible? Till recently the answer would have been in the affirmative, but it was now seen to be incompatible with Weissmann's theory. That theory was based on the continuity of the germ plasm, which was not manufactured afresh within the individuals of each generation, but was handed on from generation to generation. Men were not links in a chain of life, but rather flowers and leaves, which sprang from a common stem, the germ plasm. The reason for the resemblance of successive generations was that they were all formed out of the same stuff to the design of the same Architect. If a body suffered from any deep seated disorder of nutrition, the germ plasm probably suffered, too. It was said that there could be no inheritance of microbic disease, but might not susceptibility or power of resistance to such disease be first acquired and then inherited? Another problem was that of whether the laws enunciated by Mendel with regard to the transmission of dominant characters were applicable to man in health and disease. The only way to deal with it was by the collection of pedigrees, which must be complete both for normal and for diseased members.

After the delivery of the oration the president, Sir Douglas Powell, presented the Bisset-Hawkins medal, awarded triennially to a British medical man who had distinguished himself in sanitary science and the promotion of public health, to Sir Shirley Murphy, medical officer of health to the London County Council, in recognition of his services to the

public and to preventive medicine.

The handsome new Manchester Royal Infirmary is now completed and will be open to inspection by the public this week. Its erection in an open and healthy part of the city, about half a mile from the medical school, has occupied about 650 men for three years. The infirmary consists of forty-eight separate blocks of buildings, all connected by covered ways. Of the 592 beds provided, 240 are for medical and 300 for surgical cases. Twenty are reserved for gynæcological cases and thirty-two for ophthalmic cases. The surgical beds are distributed over five units, each of which has its own operating theatre, with anæsthetizing, recovery, sterilizing, testing, and apparatus rooms, and its own classroom attached. The medical side also com-

prises five units, each with a clinical laboratory and a classroom attached. The medical board of the infirmary assisted in the preparation of the specifications, and the result is that the hospital is one of the finest in the world for the treatment and study of disease and for the instruction of students. Expenditure upon the building has amounted to £500,-000. Of this amount, £400,000 was received from the Manchester City Council for the site of the old infirmary in the centre of the city. A public appeal was made for the remaining £100,000, in order that the new building should be opened free from debt, with its endowments intact. In response, nearly £75,000 has already been received. An appeal has also been issued for increased annual subscriptions, as it is estimated that the cost of maintaining the new establishment will be £12,000 a year more than that of the old one. Another hospital in Manchester, the Jewish, has been enlarged recently, and Mr. Winston Churchill, the president of the Board of Trade, opened a new wing last week. This institution is the only Jewish hospital in the kingdom, and has been in existence about five years. It has now forty beds and a large outpatient department, and, in consequence of the removal of the infirmary from the centre of the city, will probably have to be further enlarged in the near future.

The Children's Bill has been occupying the attention of the House of Commons since its reassembly for the autumn session, on October 12th. Mr. Herbert Samuel, under secretary for the Home Office, is in charge of the bill, and considerable progress has been made with it. An important provision of the bill deals with the overlying of infants. Mr. Samuel, in moving the clause, stated that about 1.600 infants lost their lives yearly from overlying in England and Wales, and said that there could be no doubt that drunkenness had much to do with the evil, for official statistics proved that cases occurred twice as often on Saturday nights as on the other nights of the week, and twice as often in weeks containing bank holidays as in other weeks. The existing law was inadequate, because the only charge under which the offender could be punished was that of manslaughter, and coroners' juries were naturally reluctant to bring in a verdict which would expose the mother to so serious an accusation. The bill provides that, if an infant meets its death by overlying, the offending person being over sixteen years of age, and having been at the time of going to bed under the influence of drink, shall be "deemed to have neglected the child in a manner likely to cause injury to its health,' and so to become liable to punishment under the act. The clause was passed by a majority of 125.

Therapeutical Motes.

The Treatment of Lead Poisoning.—The following prescriptions are quoted by Pron (Formulance synthetique, 1968):

| 11 | Pota num rodide, | | 11 |
|----|----------------------------|--------------------|----|
| | Di tilled water, | | 30 |
| M. | et Sig.: One tablespoonful | to be taken daily. | |

Two sulphur baths should be taken during the week.

The following powder should be given in one to two teaspoonful doses in half a glassful of water the first thing in the morning before any food is taken:

| Ŗ. | Sublime Cream | | | | | | | | | | | | | | .3v |
|----|------------------|--|--|--|---|--|--|------|--|--|--|------|--|----|---------|
| M | Sugar o | | | | ٠ | | | | | | | | | āā | 3iiss. |

A quarter of an hour before the two principal meals of the day give a teaspoonful of the following mixture:

| P, | Extract of cinchona, Fluidextract of kola, | c |
|-----|--|---|
| | Alcohol, | |
| 3.6 | Glycerin,q. s. ad. 3i | |

To overcome the paralysis apply the continuous current.

Treatment of Acute Laryngitis.—Mendel advises repose in bed in a room guarded from noise, with the inhalation three times a day, morning, noon, and night, for three to five minutes at a time, of the following solution contained in a suitable atomizer:

| $\mathbf{P}_{\!\scriptscriptstyle{k}}$ | Balsam of Peru,gr. viiss; |
|--|--|
| | Tincture of benzoin, Tincture of eucalyptus, |
| | Tincture of soap bark, |
| | Cherry laurel water, |
| | Distilled water, |
| M | |

The patient should be cautioned not to use the solution too freely at first, as it may prove irritating. If the parts are very sensitive and the solution causes irritation its use should be stopped.

Application for Toothache.—The following solution is recommended to be applied on a pledget of cotton to the cavity of the tooth:

| \mathbf{B} | Crystals of carbolic acid, | iss |
|--------------|--|-------|
| | Gum camphor, | |
| | Menthol, | |
| | turate in a mortar until liquefaction takes place, | and |
| then a | add the following mixture: | |
| | Chloroform, | . 3ii |

For Tenia in Adults.—Peschier is cited in La Clinique for September II, 1908, as the author of the following formula for the removal of intestinal worms:

M.

| \mathbf{R} | Calomel,gr. ix; |
|--------------|--|
| | Pulverized tin, |
| | Gum acacia,ää gr. xx; |
| | Oleoresin of male fern,gr. xl; |
| | Pulverized male fern root,q. s. |
| | fac pil. No. xx, and coat with silver. |
| Sig | . Ten pills to be taken in the evening at 10 o'clock |

Lotion for Cracked Nipples—A Correction.— The quantities ordered in the prescription for cracked nipples, by Marfan, printed in the *New York Medical Journal* for October 24th, page 796. should be read as grammes, and not grains, as the abbreviation "gr." would seem to indicate. In its corrected form, the formula reads:

and the remainder of the pills thirty minutes afterwards.

| 3x |

NEW YORK, SATURDAY, NOVEMBER 7, 1908.

A NATIONAL "DEPARTMENT" OF PUBLIC HEALTH.

In the Presidential campaign which has now come to a close the platforms of the two most prominent parties made certain professions which were interpreted as signifying the willingness of both those parties to enact Congressional legislation having for its object the establishment of a national public health body charged with all the duties and powers that are now distributed among several bureaus in different departments of the general government. We doubt, however, if either of those parties really meant to do such a thing, and we doubt if its advocacy in a Presidential message would result in the establishment of such a national body. The platform sections alluded to may have been sops to Cerberus, and in this instance Cerberus does not appear to us to be a very formidable

For years past there have been frequent demands on the part of various medical organizations for the creation of a "department" of public health. Until recently the more prominent advocates of the policy have demanded that the head of the "department" should be a member of the President's Cabinet, but this aspiration seems latterly to have been given up, perhaps because it has come to be recognized that the Cabinet is already unwieldy and that no President would look favorably upon its further increase. At the most, a bureau would answer, and that, as we understand it, is all that is now asked for. But we have at present an admirable bureau, the Pub-

lic Health and Marine Hospital Service, charged with the main duties that would properly belong to any bureau of public health, if we except that of the registration of vital statistics, a work which the Bureau of the Census is well equipped to perform.

It seems to us that national health functions must of necessity be to some extent distributed among several bureaus, and we cannot conceive that the Bureau of Animal Industry, for example, will ever feel itself warranted in discontinuing its present activities, no matter what form of centralized sanitary service may be established. It has done good work and is doing it continually, and we are unable to see what would be gained by merging it in some new bureau or by taking it away from the Department of Agriculture or by withdrawing the Public Health and Marine Hospital Service from the Treasury Department and handing it over to the Department of the Interior, for example. It makes no difference to the country what Cabinet officer is set over a bureau, provided the bureau itself is efficiently organized and furnished with adequate powers and resources.

We have great reason to be proud of our Public Health and Marine Hospital Service. Like all other human institutions, it can of course be improved and strengthened, and we should all labor to bring about the full efficiency of which it may be made capable. Such a result is not at all likely to be attained, it seems to us, by merging its functions in those of a new bureau which must be more or less experimental and subject to disturbing political machinations. The American Public Health Association, certainly a most intelligent body of men, expressed itself, at the recent Winnipeg meeting. in favor of the utmost support of the bureau, and it will generally be conceded, we think, that the members of that association understand quite as well as any other body of men what is best for the sanitary interests of the country.

MORBIDITY STATISTICS.

It was a notable paper, entitled The Purposes and Objects of Morbidity Statistics and the Methods of Collecting Them, which was read by Assistant Surgeon General Eager, of the United States. Public Health and Marine Hospital Service, before the Section in Vital Statistics of the American Public Health Association at the recent meeting in Winnipeg. We present the entire paper in this issue and we desire to call our readers' particular attention to it. It is not alone on account of General Eager's exceptionally direct and sententious diction that the paper seems to us admirable; the facts and deductions which he presents are in the highest degree important, for it is quite as much from the

prevalence of certain diseases as from their fatality—more, indeed, we should say—that data that will prove useful may be obtained.

While General Eager's whole communication should be read carefully, there are certain points that seem to be of special interest. In the first paragraph he remarks upon the silence of the present mortality statistics as to the frequent termination of diseases of the heart and bloodvessels, cirrhosis of the liver, and Bright's disease in fatal tuberculous trouble, and of diabetes in acute pneumonia. We are confident that this defect of our mortality returns will be in great measure remedied by changes in the reporting methods that may be looked for as the result of the earnest and intelligent efforts now being made by such men as Dr. Cressy L. Wilbur, of the Bureau of the Census, and Dr. Wilmer R. Batt, of the Pennsylvania State Board of Health. However, it will take time for their labors to bring about the end desired.

General Eager mentions the extraordinary mortality from measles in the Faroe Islands in 1846 and in the Fiji Islands in 1875. We may recall, also, that measles was the cause of a great amount of incapacity for military duty, and no low source of mortality, among the Federal volunteers in the early stage of our civil war. In regard to another point General Eager says: "On the other hand, death returns in the case of a highly mortal but slightly diffused disease may give rise to false inferences as to the extent of the prevalence." We may suppose that cerebrospinal fever furnishes a conspicuous example of such false impressions. relation of diseases to climate, seasons, altitude, latitude, and soil, mentioned by General Eager, was anticipated to a great extent by the late Dr. Bowditch, of Boston, in his investigations as to the ætiology of tuberculous disease. The question of the relation of injuries and occupational diseases to the matter of employers' liability, likely soon to claim the attention of legislators on a large scale, is sketchily but effectively touched upon by General Eager. It is interesting to be reminded that, according to the census of 1890, sickness of all sorts, together with disability consequent on recent accidents, happened to be less prevalent on a certain day in the great cities of the country than in suburban and rural communities.

Compulsory registration of certain diseases, to be extended ultimately to all diseases, is regarded by General Eager as the only feasible plan for the collection of morbidity statistics. As regards the morbidity returns tabulated in the *Public Health Reports* of the United States Public Health and Marine Hospital Service, General Eager records his belief that the returns of yellow fever and the Ori-

ental plague are as complete as it is possible to make them, and that those of smallpox are constantly improving.

ECTOPIA OF THE TESTICLE.

It is impossible to give any hard and fast rules of treatment for cases of imperfectly descended testicle, because they vary so much in their features. There are two points of great importance to be borne in mind-the imperfect descent and the imperfect development of the organ. To improve the imperfect descent by operation does very little good. Indeed, although much can be done by operation to cure the imperfect descent, it is unfortunate that little can be done to improve the imperfect development. We cannot make the testicle grow to full size and maturity if it is not so designed. In consequence, operations intended merely to cure the imperfect descent of an imperfectly descended testicle must fall into disrepute for the reason that they do not improve the development of the gland, which is by far the more important element. Thus, by neglecting the question of the future development of the gland, the results of orchidopexy are unsatis-

But not only does this operation not improve the development of the imperfectly descended testicle, but often it is actually productive of harm by causing venous congestion and inflammation of the gland. Tersely, it may be stated that orchidopexy is an operation which fails very often both anatomically and physiologically-anatomically, because the gland, if fixed in the scrotum, seldom remains there; physiologically, because the testicle is largely converted into useless connective tissue instead of useful epithelium. Except in very carefully selected cases it is not infrequently a dangerous operation. But, as it has hitherto been the most popular intervention for ectopia of the testicle, it is necessary, having condemned it, to examine very carefully into the other lines of treatment left to us. These are three. The first of them is to leave the case alone. This line of treatment can be pursued safely until one or any of the following occur: 1, Attacks of pain in the testicle. 2, Attacks of inflammation of the gland. 3, Hardening of the testicle. 4, Dilatation of the inguinal canal with or without the development of a hernia. The second is orchidectomy. This is justifiable only when there is a torsion of the spermatic cord, the testicle being much sclerosed and the patient at least twenty-two years of age. Thirdly, we have orchidocælioplasty. This is the most useful operation from the standpoint of the patient, because it neglects the comparatively unimportant imperfect descent of the testicle

and it tends to remedy the all important imperfect development of the gland. An imperfectly descended testicle can rarely if ever elaborate spermatozoids, so that its whole value may be taken to lie in its internal secretion, which is fostered by the abdominal reposition of the gland, and not in its external secretion. The reposition can be done in two ways—an extraperitoneal and an intraperitoneal orchidocolioplasty. The latter is preferable, the gland being placed under conditions similar to those of the ovary. Increased liability of the onset of malignant disease is not incurred after this operation, because it is not the abdominal position of the organ, but the concurrent imperfect development, which gives it its proclivity to become malignant.

From what has been said, particularly as to the four occurrences which should terminate the period of treatment by waiting—pain, inflammation, sclerosis, and dilatation of the inguinal canal—it will be seen that very few cases of ectopia of the testicle will escape operation, more particularly when it is recalled that about eighty per cent. are associated with a hernial sac. The operation is particularly indicated in cases of movable testicle, with slight imperfections of descent, and in patients from seven to ten years of age.

THE PERIOD OF MENTAL ACTIVITY.

Dr. W. A. Newman Dorland, of Philadelphia, has written a little book' in refutation of Dr. William Osler's reputed dictum that most men were intellectually useless after the age of sixty. Dr. Dorland has examined the histories of 400 of the great men of modern times from the point of view of the period of life in which their opera maxima were produced. He divides the men into "thinkers" and "workers." This division may seem crude, for the two classes must to a great extent overlap; but it is convenient for the author's purpose.

The gist of Dr. Dorland's data may be extracted from a tabular statement which he gives at the close of the book. It appears from the table that the following great "thinkers" did not cease work until they were sixty years old or more: Astronomers and mathematicians.—Arago, Biot, Copernicus, D'Alembert, Euler, Galileo, Herschel, Lagrange, Laplace, Leverrier, Napier, and Newton. Clergymen.—Alford, Beecher, Chalmers, Farrar, Mather, Moody, Newman, Sydney Smith, Stanley, and Wesley. Dramatists.—Boucicault, Corneille, Ibsen, and Jonson. Essayists.—Arnold, Burton, Carlyle, Curtis, De Quincey, Isaac Disraeli, Emerson, Gree-

ley, Baron von Grimm, Holland, Holmes, Leigh Hunt, Johnson, La Rochefoucauld, Littré, Lowell, Max Müller, Paulding, Rousseau, Ruskin, Sainte-Beuve, and Voltaire. Historians.—Bancroft. Boeckh. Freeman, Froude, Grote, Hallam, Irving, Lamartine, Michelet, Milman, Mommsen, Montesquieu, Motley, Parkman, Pepys, Ranke, and Renan. Jurist.—Savigny. Naturalists.—Agassiz, Audubon, von Baer, Buffon, Cuvier, Darwin, Geoffroy St .-Hilaire, Humboldt, Huxley, Lacépède, Lamarck, Leidy, Linnæus, Lyell, Pasteur, and Tyndall. Novelists. - Andersen, Balzac, Blackmore, Bulwer, Chateaubriand, Collins, Cooper, Defoe, Du Maurier, Ebers, Gautier, Jacob Grimm, Wilhelm Grimm, Hugo, Le Sage, Lever, Lover, Reade, Richardson, Scott, Trollope, Verne, Wallace, Warren, and Zola. Philosophers.—Bacon, Berkeley, Condillac, Diderot, Hegel, Hobbes, Kant, Leibnitz, Locke, Lotze, Mill, Saint-Simon, Schelling, Schopenhauer, Adam Smith, and Spencer. Poets.—Arnold, Béranger, Browning, Bryant, Chaucer, Coleridge, Cowper, Dryden, Goethe, Keble, La Fontaine, Landor, Longfellow, Lytton, Milton, Petrarch, Southey, Tennyson, Watts, Whitman, Whittier, Wordsworth, and Young. Reformers.—Cranmer, Erasmus, Fénélon, Fox, Knox, Laud, Loyola, Luther, Melanchthon, Swedenborg, and Wycliffe. Satirists and humorists.—Butler, Cervantes, Rabelais, and Swift. Statesmen.-John Adams, Bismarck, Blaine. Bolingbroke, Bright, Baron von Bunsen, Burke, Calhoun, Clay, Crispi, Disraeli, Franklin, Gallatin. Garibaldi, Garrison, Gladstone, Guizot, Hastings, Hay, Patrick Henry, Jefferson, Richard Henry Lee, Monroe, Robert Morris, Lord Palmerston, Sir Robert Peel, Penn, Talleyrand, Thiers, Walpole, Washington, and Webster.

Among the "workers" who continued their activity until they were sixty years old or older are enumerated: Actors.-Forrest, Garrick, Irving, Jefferson, and Kemble. Artists.—Blake, Botticelli, Bouguereau, Constable, Corot, Cruikshank, Gainsborough, Hogarth, Landseer, Leonardo da Vinci, Meissonier, Michael Angelo, Miller, Murillo, Perugino, Rembrandt, Reynolds, Romney, Rubens, Tintoretto, Titian, Turner, Velasquez, Veronese, West, and Wren. Chemists and physicists.—Boyle, Dalton, Faraday, Gay-Lussac, Liebig, and Priestley. Explorers. - Burton, Champlain, Columbus, Du Chaillu, Franklin, Livingstone, Raleigh, Rennell, Ritter, Schliemann, and Stanley. Inventors.-Bessemer, Morse, Stephenson, and Watt. Musical composers.—Bach, Brahms, Gluck, Gounod, Händel, Haydn, Liszt, Meyerbeer, Rossini, Spohr, Verdi, and Wagner. Physicians and surgeons.-Boerhaave, Sir Astley Cooper, Harvey, John

The Age of Mental Virility. An Inquiry into the Record of Achievement of the World's Chief Workers and Thinkers. By W. A. Newman Dorland. New York: The Century Company, 1908

Hunter, Jenner, Rush, and Virchow. Warriors .-Grant, Robert E. Lee, Marlborough, von Moltke, Napier, Sherman, and Wellington.

The lives of not a few of the great men of the world have come to an untimely end, and some of them are included in the 400 studied by Dr. Dorland; otherwise he might have been able to make a still stronger showing for men sixty years of age or older. So far as his facts go in this direction, they are a notable addition to those that have been adduced by others toward the refutation of Dr. Osler's reputed dictum. But the book deals with other matters also, such as precocious intellectual development and the relations of genius to degeneracy and insanity. It is a very entertaining essay.

THE NEW VOLUME OF THE INDEX CATALOGUE.

The thirteenth volume of the second series of the Index Catalogue of the Library of the Surgeon General's Office, United States Army, has just been received. It carries the vocabulary from Periodicity to Prussia. In his letter of presentation to the surgeon general Major Walter D. McCaw, of the Medical Corps, states that the library now contains 165,342 bound volumes and 291,346 pamphletstruly a priceless collection. The volume includes the fourth addition to the alphabetical list of abbreviations of titles of medical periodicals published in the ninth volume of the second series. The 929 pages, of large size and close print, bear testimony to the fidelity with which this great work is prose-

Rems Stems.

Changes of Address.—Dr. Stillwell C. Burns, to 247 South Thirteenth Street, Philadelphia.

South Thirteenth Street, Philadelphia.

The Second Harvey Lecture will be delivered by Dr. W. G. MacCallum, of Johns Hopkins University, on Saturday, November 7th, at 8:30 p. m., at the New York Academy of Medicine. The subject will be Fever.

The Atlantic City Municipal Hospital was dedicated on Wednesday, October 21st. Addresses were made by Dr. Henry Beates, of Philadelphia; Dr. A. Bruce S. Kester, of the New Jersev State Board of Health, and Dr. A. C. Abbott, of Philadelphia.

The Buffalo Academy of Medicine.—A meeting of the Section in Medicine will be held on Tuesday evening, Newsmitz 10tl. Five principal feature of the programme

the Section in Medicine will be held on Tuesday evening, New inher toil. Five principal feature of the programme will be a paper by Dr. Solomon Solis-Cohen, of Philadelphia, on the Place of Drugs in Medicine.

The Rochester, N. Y., Academy of Medicine—A meeting of Section I, which embraces general medicine, neurology, psychiatry, materia medica, and therapeutics, was held on Wednesday evening, November 4th, at the Rochester State Hospital. Dr. E. L. Hanes, of Flushing, L. I., read a paper on Manic Depressive Insanity.

Chicago Medical Society—A regular meeting of this

1. I., read a paper on Manic Depressive Insanity. Chicago Medical Society.—A regular meeting of this society was held on Wednesday evening, October 28th. Dr. Leon Feingold reported a case of ischæmia of the lower extremities necessitating amputation. Dr. M. R. Barker read a paper on the Motility of the Stomach as a Valuable Factor in the Diagnosis of Gallstone Diseases. Dr. D'Orsay Hecht read a paper entitled Deep Infiltrating Injections in the Treatment of Sciatica, and Dr. D. N. Eisendrath read the Treatment of Sciatica, and Dr. D. N. Eisendrath read a paper on 12 or 1 or 1 The Montgomery County, Pa., Medical Society held a stated meeting on Wednesday, October 21st, at Pottstown. Dr. H. H. Whitcomb, of Norristown, read a paper on Tuberculosis of Bones, and Dr. William H. McKenzie, of Norristown, read a paper on Rhachitis. Dr. J. Lawrence Isenberg, of Norristown, president of the society, was in

The Medical Society of Saratoga County, N. Y., held its annual meeting recently in Mechanicsville, N. Y., and elected the following officers to serve for the ensuing year: President, Dr. W. C. Crombie, of Mechanicsville; vice president, Dr. J. R. McElroy, of Jonesville; secretary, Dr. J. T. Sweetman, of Ballston Spa; treasurer, Dr. T. E. Bulard, of Schuylerville.

lard, of Schuylerville.

Officers of the Philadelphia Pathological Society.—At a meeting of the society, held on October 22d, the following officers were elected: President, Dr. Joseph McFarland; vice presidents, Dr. A. J. Smith, Dr. David Riesman, Dr. David L. Edsall, and Dr. A. O. J. Kelly; secretary, Dr. R. S. Lavenson; treasurer, Dr. C. Y. White; recorder, Dr. F. H. Klaer; curator, Dr. E. H. Goodman.

The Superintendency of Bellevue Hospital.—Dr. Samuel T. Armstrong, who has been medical superintendent of Bellevue and Alliad Hospitals since July 12, 1005-182 for

Bellevue and Allied Hospitals since July 13, 1905, has resigned his position. The vacancy will be filled by the selection of some one whose name will appear on a new Civil Service list which the corporation counsel has been instructed to prepare. The selection rests with the board of trustees of the hospitals.

instructed to prepare. The selection rests with the board of trustees of the hospitals.

The Bristol South District Medical Society.—The semiannual meeting of this society will be held in New Bedford, Mass., on Thursday, November 12, at 5 p. m. The subject selected for discussion is the Bier Treatment, and the following papers will be read: Description and General Indications, by Dr. M. B. Swift; Application to Cases, by Dr. H. D. Prescott; Application to Chronic Cases, by Dr. H. C. Kirby.

The Elmira, N. Y., Academy of Medicine.—A meet ing of this academy was held on Wednesday evening, November 4th, in the new room of the society in the Federation Building. The programme included the following papers: Distrust of Drugs, by Dr. G. V. R. Merrill, of Elmira; Hygienic Errors in Rural Schools, by Dr. A. M. Loope, of Wellsburg, N. Y.; The Relation of Pleurisy to Tuberculosis, by Dr. F. C. Annabel, of Elmira.

Contagious Diseases in Chicago.—There were reported to the Department of Health of the City of Chicago 556 cases of contagious diseases during the week ending

556 cases of contagious diseases during the week ending October 24, 1908, this being an increase of 142 over the preceding week and of 277 over the corresponding week of last year. Of the total number of cases 171 were of diphlast year. Of the total number of cases 1/1 were of diputeria, 158 of scarlet fever, 89 of typhoid fever, 57 of tuber-culosis, 34 of measles, 20 of pneumonia, 15 of chickenpox, 6 of whooping cough, 1 of smallpox, 1 of puerperal fever, and 6 of diseases of minor importance.

The Health of Pittsburgh.—During the week ending October 10, 1908, the following cases of transmissible dis eases were reported to the Bureau of Health: Chickenpox. cases were reported to the butcau of freath. Children Scases, o deaths; scarlet fever, 27 cases, 3 deaths; diphtheria, 22 cases, 1 death; measles, 8 cases, 0 deaths; whooping cough, 7 cases, 1 death; pulmonary tuberculosis, 19 cases, 14 deaths. The total deaths for the week numbered 162, in an estimated

population of 565,000, corresponding to an annual death rate of 14.92 in 1,000 population.

Keokuk Medical College Closed.—On October 23, 1908, the Keokuk, Iowa, Medical College, the oldest medical college west of the Mississippi River, closed its doors. This institution was founded over sixty years ago, and was the first medical college anywhere in the world to admit women on the same terms with men. It is reported that the college equipment has been sold to Drake University, in Des Moines, and arrangements have been made by that college to receive the students who had registered at the Keokuk College. Much regret is expressed by the residents of Keokuk at the passing of one of the landmarks of

The Mortality of Chicago. - During the week ending October 24, 1908, there were reported to the Department of Health of the City of Chicago 510 deaths from all causes, as compared with 550 for the previous week and 509 for the corresponding period in 1507. The annual death rate in 1,000 population was 12.28, in an estimated population of 2,166.055. The principal causes of death were: Apoplexy, 15 deaths; Bright's disease, 37 deaths; bronchitis, 18 deaths; consumption, 42 deaths; cancer, 30 deaths; diptheria, 20 deaths; heart diseases, 46 deaths; intenza, 1 death; intestinal diseases, acute, 60 deaths; nervous disdeaths; nectains discases, acute, or deaths; nervous dis-eases, 10 deaths; pneumonia, 53 deaths; scarlet fever, 11 deaths; suicide, 8 deaths; typhoid fever, 11 deaths; violence (other than suicide), 29 deaths; all other causes, 119

Charitable Bequests.—By the will of John F. Murphy the Little Sisters of the Poor, of Philadelphia, the Catholic Home for Destitute Children, Philadelphia, and St. Vincent's Home, Philadelphia, receive \$200 each.

By the will of Andrew W. Evans, St. Christopher's Hoscittle Scarce Sea

pital receives \$200.

By the will of Horace Everett the Hayes Mechanics' Home and the Home for Incurables, Philadelphia, become

two of three reversionary legatees.

By the will of John J. Emery, the Children's Hospital of the Protestant Episcopal Church, Cincinnati, Ohio, receives an endowment fund of of \$20,000.

The Northwestern Medical Society, Philadelphia, held a stated meeting on Monday evening November 2d. The programme consisted of a "symposium" on pleurisy. Dr. Joseph MacFarland read a paper on the bacteriology and pathology of pleurisy. Dr. James M. Anders read a paper dealing with the general ætiology and points in the paper deating with the general actioney and points in the diagnosis. Dr. William Egbert Robertson read a paper entitled The Discrimination of Certain Conditions Likely to be Confused with Pleurisy. The medical treatment of the disease was the subject of a paper by Dr. Judson Daland, and the operative treatment was discussed by Dr. William S. Rodman.

Scientific Society Meetings in Philadelphia for the Week ending November 14, 1908:

Monday, November oth.—Section in General Medicine, College of Physicians; Wills Hospital Ophthalmic So-

Tuesday, November 10th—Philadelphia Pædiatric Society; Botanical Section, Academy of Natural Sciences.
Wednesday, November 11th—Philadelphia County Medical Society.

ical Society.

THURSDAY, November 12th.—Pathological Society; Section Meeting, Franklin Institute.

FRIDAY, November 12th.—Northern Medical Association; West Branch, Philadelphia County Medical Society.

Hartford County (Conn.) Medical Association.—A regular meeting of the surgical section of this association was held on Monday evening, October 26th. After the presentation of a number of patients and specimens, Dr. presentation of a number of patients and specimens, Dr. E. R. Lampton reported two cases of transfusion of blood, and Dr. Oliver C. Smith reported some recent cases of surgery of the neck. The remainder of the programme consisted of a "symposium" on blood transfusion. A paper on the history of the transfusion of blood was read by Dr. Arthur J. Wolff. Dr. E. J. McKnight read a paper dealing with the indications and contraindications for blood transfusion. Dr. George N. Bell read a paper describing the operative technique. The general discussion which followed was opened by Dr. M. M. Johnson and Dr. T. N. Hepburn.

Infectious Diseases in New York:
We are indebted to the Bureau of Records of the Department of Health for the following statistics of new cases and deaths reported for the two weeks ending Octo-

Ninth District of the Ohio Medical Society. sixth annual meeting of this society will be held in Ports mouth, Ohio, on Thursday, November 12th. An excellent programme has been prepared, consisting of a long list of programme has been prepared, consisting of a long list of papers on subjects of interest to the general practitioner by well known physicians. The annual banquet will be held in the evening. The officers of the society are: Councilor, Dr. John E. Sylvester, of Wellston; president, Dr. L. F. Roush, of Pomeroy; secretary and treasurer, Dr. J. S. Rardin, of Portsmouth; vice-presidents, Dr. W. M. Miller, of Gallia County; Dr. J. J. McClung, of Jackson County;

of Gallia County; Dr. J. J. McClung, of Jackson County; Dr. Lester Keller, of Lawrence County; Dr. C. M. Mooney, of Pike County; Dr. A. L. Test, of Scioto County, and Dr. W. T. Cherry, of Vinton County.

College of Physicians of Philadelphia.—A stated meeting of the college was held on Wednesday evening, November 4th, at 8 o'clock. Dr. G. G. Davis exhibited a patient showing the results of an operation for irreducible congenital luxation of the hip in an adult. Dr. Edward J. Wood, of Wilmington, N. C., read, by invitation, a paper entitled Studies of the Ætiology, Pathology, and Symptom-atology of Pellagra, with Reference to its Endemic Ocentitled Studies of the Athology, Pathology, and Symptom-atology of Pellagra, with Reference to its Endemic Oc-currence. A paper on the Operative Treatment of Papil-locdema (Choked Disc), with Special Reference to Decom-pressing Trephining, was presented by Dr. George E. de Schweinitz and Dr. T. B. Holloway. The honorary librarian reported the addition of sixty-eight volumes to the library. The chairman of the Mütter Museum an-nounced the gift of a set of dental instruments used by ship surgeons about the year 1818 during their long voy

The Alvarenga Prize.—The College of Physicians of Philadelphia announces that the Alvarenga Prize for has been awarded to Dr. William T. Shoemaker, of Philadelphia, for his essay entitled Retinitis Pigmentosa, with Analyses of Seventeen Cases Occurring in Deaf Mutes, Including Laboratory Examinations of the Blood and Urine in Eleven Cases. The next award of this prize, which con sists of the income for one year of the bequest of the late Señor Alvarenga, amounting to about \$180, will be made on July 14, 1900, provided that an essay deemed by the Committee of Award to be worthy of the award is received. Essays intended for competition may be upon any subject in medicine, must be based upon original work, must be typewritten, must be sent without signature in a sealed envelope, having on its outside the motto of the paper and within the name and address of the author, and Thomas R. Neilson, on or before May 1, 1909.

The Philadelphia Academy of Surgery.—The follow-

ing papers were read at a stated meeting of this academy, held on Monday evening, November 2d: Some Experiences in Removing the Vermiform Appendix in Cases that had been Operated on, by Dr. George G. Ross; (1) Shoulder Joint Amputation for Emphysematous (Traumatic) Gargane, (2) Temporary, Persivic of the Left Vocal Cord (2) Temporary Paralysis of the Left Vocal Cord grene, (2) Temporary Paralysis of the Left Vocal Cord after Excision of Tuberculous Cervical Lymph Nodes, by Dr. A. P. C. Ashhurst; (1) Report of a Case of Acute Pancreatitis, (2) Remarks upon the Relative Merits of Suprapubic and Perineal Prostatectomy, with exhibition of specimens of the prostate gland, by Dr. John B. Deaver; The Value of the Cammidge Reaction in the Diagnosis of Pancreatic Disease, by Dr. Edward H. Goodman; (1) The Result after Seven Years of an Open Operation for Congenital Dislocation of the Kinege (2) Report of 2 Case

Pancreatic Disease, by Dr. Edward H. Goodman; (1) The Result after Seven Years of an Open Operation for Congenital Dislocation of the Knee, (2) Report of a Case Illustrating the Value of Delay in the Reduction of Herniæ, Apparently Gangrenous, by Dr. John B. Roberts.

Society Meetings for the Coming Week:

Monday, November 9th.—New York Academy of Medicine (Section in Neurology and Psychiatry); Society of Medical Jurisprudence, New York; New York Ophthalmological Society; Corning, N. Y., Medical Association; Waterbury, Conn., Medical Association; Waterbury, Conn., Medical Association; Cuesnay, November 10th.—New York Academy of Medicine (Section in Public Health); Medical Society of the County of Rennsselaer, N. Y.; Buffalo Academy of Medicine (Section in Medicine); Newburgh Bay, N. Y., Medical Society; New York Obstetrical Society.

Wednesday, November 11th.—New York Pathological Society; New York Surgical Society; Medical Society of the Borough of The Bronx; Alumni Association of the City Hospital, New York; Brooklyn Medical and Pharmaceutical Association; Medical Society of the County of Richmond, N. Y.

Thusbay, November 12th.—New York Academy of Medical Society of the County of Richmond, N. Y.

Pharmaceutical Association; Medical Society of the County of Richmond, N. Y.
THURSDAY, November 12th.—New York Academy of Medicine (Section in Pædiatrics); Brooklyn Pathological Society of Rochester, N. Y.; Jenkins Medical Association, Yonkers, N. Y.
FRIDAY, November 12th.—New York Academy of Medicine (Section in Otology); New York Society of Dermatology and Genitourinary Surgery; Eastern Medical Society of the City of New York; Saratoga Springs, N. Y., Medical Society.
Syturnay, Vorcember 11th.—Therapeutic Club, New York.

SATURDAY, Voi curber 14th. Therapeutic Club, New York.

Special Lectures by Dr. Dock at Tulane.—Dr. George Dock, professor of the theory and practice of medicine at the Tulane University of Louisiana, and formerly of the University of Michigan, will deliver a course of ten special lectures, which are open to members of the medical pro-fession, as well as to medical students. The first lecture was given on the evening of October 28th, and the second was given on the evening of October 28th, and the second on November 4th, the subject of both lectures being Addison's Disease. The third lecture will be given on Wednesday evening, November 18th, on the subject of the Thyreoid Gland—Anatomy, Physiology, Chemistry, Functions. Diseases of the Thyreoid Gland will be the subject of the fourth lecture of the series, which will be delivered on Tuesday evening, November 24th. The fifth, sixth, and seventh lectures will be on Goître, and will be held on December 2d, 9th, and 16th, respectively. The subject of beceining 13th, and will be delivered on January 6th, will be Sporadic Cretinism, and the ninth lecture will be on January 13th, and will deal with the Pituitary Body. The last lecture in the course will occur on January 20th, the subject being Osteomalacia.

Meetings of Sections of the New York Academy of Medicine.—The Section in Neurology and Psychiatry will meet on Monday, November 9th, at 8:15 p. m. After the presentation of patients and the reports of cases, Dr. August Hoch will read a paper entitled A Study of Neutral Makeup in Different Functional Psychoses.

The Section in Dermatology will hold a meeting on Tuesday evening, November 10th, at 8:15 o'clock. The programme will consist of the presentation of cases and a

general discussion.

On Thursday, November 12th, at 8:15 p. m., a meeting of the Section in Pædiatrics will be held. Dr. W. P. Northrup will report a case of obstinate vomiting cured by what is possibly a new method. Dr. Kaufman Schlivek will report a case of ulcerative endocarditis with necropsy and blood findings. The paper of the evening will be read by Dr. E. W. Scripture on Tics in Children and their Treatment. The Section in Otology will meet on Friday evening, November 13th, at 8:15 o'clock. Dr. M. D. Lederman will be read by the property of th

November 13th, at 8:15 o'clock. Dr. M. D. Lederman will present a patient, fifteen years of age, with chronic suppurative oftis during pregnancy, with pulmonary abscess and other complications. Dr. W. S. Bryant will present a patient with chronic mastoiditis. Specimens of large mastoid sequestrum will be presented by Dr. W. C. McFarland and Dr. J. B. Rae, and modifications of Gelle's experiment and device for their production will be demonstrated by Dr. Edmund Prince Fowler. Dr. Robert Lewis, Ir. will report a case of cavernous sinus thrombosis oc-Jr., will report a case of cavernous sinus thrombosis oc-curring in acute staphylococcic tonsilitis followed by death. The Section in Public Health will hold no meeting during the month of November.

Army Medical Corps Examinations.—The Surgeon General of the United States Army announces that the first of the preliminary examinations for the appointment of first licutenants in the Army Medical Corps for the year 1909 will be held on January 11, 1909, at points to be hereafter designated. Full information concerning the examination can be procured upon application to the Surgeon General, United States Army, Washington, D. C. The essential requirements to securing an invitation are that the appli-cant shall be a citizen of the United States, shall be between twenty-two and thirty years of age, a graduate of between twenty-two and thirty years of age, a graduate of a medical school legally authorized to confer the degree of doctor of medicine, shall be of good moral character and habits, and shall have had at least one year's hospital training or its equivalent in practice. The examinations will be held concurrently throughout the country at points where boards can be convened. Due consideration will be given to localities from which applications are received in order to lessen the travelling expenses of appliceived, in order to lessen the traveling expenses of appli-cants as much as possible. The examination in subjects of general education (mathematics, geography, history, general literature, and Latin) may be omitted in the case of applicants holding diplomas from reputable literary or scientific colleges, normal schools or high schools, and of graduates of medical schools which require an entrance examination satisfactory to the faculty of the Army Medical School. In order to perfect all necessary arrangements for the examination, applications must be complete and in possession of the Adjutant General on or before December 10, 1908. Early attention is therefore enjoined upon all intending applicants. There are at present fifty-seven vacancies in the Medical Corps of the United States Army.

Fractures of the Os Calcis, By Frederic J. Cotton and Louis T. Wilson.

The Ethmoid Cells at Birth and their Development during Fœtal Life, By E. J. CURRAN.

A Case of Coincident Tubal and Intrauterine Pregnancy,

By CHARLES M. GREEN and ARTHUR B. EMMONS, 2D. 4. The Serum Treatment of Epidemic Cerebrospinal Meningitis, with a Report of Twenty-two Cases,

By FRANK TAYLOR FULTON. 5. Bursitis Subacromialis, or Periarthritis of the Shoulder Joint. (Subdeltoid Bursitis),

By ERNEST AMORY CODMAN.

1. Fracture of the Os Calcis.-Cotton and Wilson remind us that comminuted fracture of the os calcis is relatively common. Nearly all cases are of substantially the same type. The results are rather frequently so imperfect as to interfere seriously with work or to disable the sufferer entirely. The cause of disability is not the fracture as such, but certain displacements, which should be remediable or rather preventable. In studying the disabled cases the authors have found the following conditions of importance: Raising of the heel, shortening of the heel, outward deviation of the heel, flattening of the arch, projection of fragments into the sole of the foot, loss of motion between the astragalus and the os calcis, mechanical interference between os calcis and external malleolus. The treatment ordinarily advocated and carried out is no treatment at We have all of us been guilty of what is very nearly criminal negligence in regard to these cases. Certain measures are practicable in the treatment of fresh cases that will minimize, or often prevent, the special displacements which are the cause of disa-Provided certain measures have not been carried out, and provided disability is present, palliation is possible by apparatus in some cases, while in others operations of no great gravity or technical difficulty will insure decided improvement of function. Given a case of fracture of the os calcis with any displacement, with loss of motion, with marked bony thickening below the outer malleolus, or with spurs, or the prospect of spur formation, toward the sole, it is our duty to interfere. And our interference should occur before any considerable repair has gone on, usually at three to seven days by choice. The routine should be: Ether. Breaking up impaction (with hands alone or with a spindle inserted beneath the heel cord). Correction of any upward or lateral displacement. Securing of adequate motion between calcis and astragalus by forced pronation and supination. Reimpaction with sand bag and mallet or by manual pressure. The authors then speak of the after treatment, for which usually an apparatus will suffice. Of the causes of disability not remediable by apparatus we have: Loss of motion in the joints, excessive bony thickening below the external malleolus, bony spurs in the sole, outward displacement of the heel, extreme upward displacement of the heel. These conditions are all essentially operative.

3. A Case of Coincident Tubal and Intrauterine Pregnancy.—Green describes such a case, in which neither the history nor the physical examination seemed to warrant a diagnosis of pregnancy, either tubal or uterine; and the probable diagnosis made was ovarian cyst with twisted pedicle, with a supervening inflammatory process. On opening the abdomen the cystlike mass was found to be the uterus, four months pregnant; and the supposed thickened and twisted pedicle was seen to be a gravid tube surrounded with from four to six ounces of blood clot, forming a mass in which the vermiform appendix was involved. Taking especial care to disturb the uterus as little as possible, the appendix and the tubal mass were removed, and the incision closed. On the same evening the fœtal membranes ruptured; four days later a slightly macerated, four months' fœtus was cast off spontaneously, and the uterus was curetted. The subsequent convalescence was uneventful. The intrauterine fœtus had apparently been dead two or three days, and if so, was alive at the time of the removal of the partly aborted tubal pregnancy.

2. Arsenic in Diseases of the Skin.—Hartzell speaks of the use of arsenic in eczema, psoriasis, lichen planus, pemphigus, dermatitis herpetiformis, sarcoma of the skin, and mycosis fungoides. He then reports his results with sodium cacodylate, and atoxyl in psoriasis. He comes to the conclusion that atoxyl, like sodium cacodylate, does not possess any therapeutic properties not to be found in arsenious acid, Fowler's solution, or sodium arsenate. Owing to its great solubility in water and freedom from irritant properties, it is, however, especially adapted to hypodermic use, a method of using arsenic often preferable to administration by the mouth and one which usually gives superior therapeutic results. About the untoward effect of arsenic which deserves the serious consideration of every one who essays to use this potent drug in chronic diseases, he thinks that it is now well established that the long continued use of arsenic, especially in considerable doses, may be followed by circumscribed keratoses on various parts of the body and more particularly on the palms and soles. He reminds us that Jonathan Hutchinson some years ago called attention to the fact that epithelioma may develop at the site of these keratoses, an observation which has since been confirmed by a number of

other observers, so that there are now at least twenty cases of such arsenical epithelioma to be found in

4. Serum Treatment of Carcinoma.—S. Strauss, of New York, has developed the following theory of cancer: The cancer elements are found in utero; that is, there is an abnormal development of the embryonal cells, which group is the starting point of a carcinomatous growth. Intermingled with the healthy epithelial cells are these cancer units, and whenever the conditions for hemming them in or retarding their growth is overcome by exciting causes, such as improper living and eating, mental worry or grief, senility, etc., they multiply very rapidly, destroying and penetrating into the surrounding tissue, giving off a toxine which in time affects the entire system. Therefore, our endeavor should be to demonstrate a cancer specific reaction in the human body by means of a serum precipitant establishing its identity, irrespective of a microscopical examination. In pursuance of this theory, in the spring of 1904 he decided that possibly the inoculation of a serum taken from the lower animals suffering from a similar malignant condition, which treatment, he says, had not then been tried, might be successfully used in the human subject with the idea of arresting the disease and eventually effecting a permanent cure. He believed that the serum contained enough antibodies to neutralize the toxine circulating in the system. He found great difficulty in the course of his studies because he stood practically alone in a new field, and, therefore, received no benefit from the work of others. The serum which he uses at present is obtained directly from the lower animals suffering from malignant growths, principally the horse; the diagnosis being substantiated microscopically. Shortly after injecting the serum the face of the patient becomes flushed; there is an increase of the blood pressure, as the serum seems to have a marked effect on the spinal centres, producing pain in the back, which radiates down the legs. In some cases a chill occurs within the first few hours. After four to six hours there is an elevation of the temperature, but not exceeding three degrees in any case observed. At times there is great restlessness for the first twentyfour hours. Strauss concludes that visceral carcinoma is incurable and fatal in nearly all cases, while superficial or surface carcinoma is curable and amenable to treatment if attended to early. Carcinoma is hereditary, the tendency to its formation being transmitted to successive generations, and it becomes evident whenever the natural restraining influences are removed. The disease is on the increase, the death rate being over seven thousand in New York State in 1907. The serum treatment should be used after every operative case to immunize the system and prevent recurrence. It raises the opsonic index and causes a leucocytosis, and it should be used in inoperable cases, because it relieves the pain and ameliorates the symptoms without interfering with the natural functions of the body.

8. "Winter Cholera."-Breitenbach says that winter cholera has no specific bacteriological pathology and is a synonym for the more common forms of bowel disturbances, choleiform in nature, oc-

curring in cold weather. The use of this term, interchangeably with the nomenclature of other gastrointestinal diseases, shows the great need of more exact phraseology, based on correct diagnosis. Meteorological conditions do not prove to be the exciting cause in these epidemics of winter cholera, but only as the factors instrumental in polluting water or milk are present, do these epidemics occur. Winter cholera, as typified by these choleiform manifestations of diarrhœa in cold weather, has no exciting cause in the activity of Pfeiffer's bacillus and does not, therefore, exemplify gastrointestinal influenza. Influenza, with a symptomatology centering itself in the gastrointestinal tract, was present during epidemics of winter cholera, but these isolated cases occurred during epidemic influenza. Diagnosis in these cases is established by proving the presence of the associated microorganism. To the end of stimulating a greater enthusiasm in demanding intelligent and adequate sanitary reform, instruction in sanitary science should demand a major consideration in the medical curriculum. Legislation controlling the watersheds and preventing contamination of public waters is imperative.

10. The Menopause.—Craig observes that there are three normal types of the menopause, sometimes seen more or less in combination with another; departures from these normal types are easily recognized; the symptomatology alone will very often point to the organ or region at fault, but such deduction should always be given physical confirmation; lesions at this time are as deserving of and amenable to treatment as at any other time; neglect of such treatment engenders inestimable, unnecessary suffering and is one of the greatest factors in causing so many malignant uterine growths to attain an inoperable state of advancement; failure to properly diagnosticate and treat such cases will inevitably bring opprobrium on our profession as a

whole.

MEDICAL RECORD. October 31, 1908.

Intestinal Infection and Immunity in Tuberculosis,

By Professor A. Calmette. The Myth and the Mystery of "Ménière's Disease," By George M. Gould.

The Epileptic Voice Sign,

By L. Pierce Clark, and E. W. Scripture.
What Factors Are Necessary in Addition to Asepsis
to Secure Healing by Primary Union?
By Richard Ward Westbrook.
Preliminary Notes upon a Case of Leprosy Apparently
Cured with the X Rays, By Victor G. Heiser.

I. Immunity in Tuberculosis.—Calmette says that upon the whole, the resistance conferred by tuberculin and that which is observed in animals or in man already attacked by benign forms of tuberculosis (tuberculosis of the lymph nodes or scrofula, tuberculosis of the bone, or of the skin, lupus) appear to be of the same nature as that which is artificially effected, whether by intravenous inoculation of human or bovine bacilli, following the methods of Behring or of Koch and Schültz, or by subcutaneous inoculation of the same bacilli (Lignières, Arloing), or by the insertion under the skin of collodion sacs containing cultures of human or bovine tuberculosis (Heymans). In each of these cases it is not a question of true immunity, since the animals thus prepared, although not giving the tuberculin reaction, remain indefinitely carriers of living and virulent bacilli, and these are capable when the resistance begins to diminish of giving rise in the bodies of these same animals to serious lesions.

3. The Epileptic Voice Sign .- Clark and Scripture observe that various characteristics follow different nervous affections, thus we have tabetic gaits, the posture of paralysis agitans, the mental stigma of epilepsy and hysteria, and the like. It seems probable that there are characteristic functional stigmata in the voices of persons suffering from nervous and mental diseases. The characteristic speech of paresis and the thin, high pitched voice of paralysis agitans are well known and readily recognized by all. Many of us have observed that there is something very peculiar and distinctive in the epileptic voice. The defect is shown in the expressionless quality of the voice; it renders the epileptic incapable of singing beautifully or speaking well. To one who has lived in a large colony for epileptics for several years the alteration of the epileptic voice is both striking and obvious. The authors have studied these changes. The method, used by them, is as follows: The patient speaks into a mouthpiece that covers his mouth rather tightly; this is connected to a small metal cup, the tambour. The top of the tambour is covered with thin rubber that yields to puffs of air and vibrations. A lever connected to the rubber receives the vibrations on a rapidly revolving smoked drum or kymograph. The arrangement can be conveniently called the "tambour method." In a list of 100 cases Clark was able to detect the disease in seventy-five per cent. of the cases by the voice sign alone. There is no precisely similar defect in any other nervous or mental disease. All types of epilepsy have been under study. One case had had but four epileptic fits and had never taken medicines for his disease. The voice sign seems to develop with the disease. The more severe the epilepsy and the longer duration it has, the more marked one finds the voice sign. The sign appears to depend upon the underlying brain degeneration, of which the epileptic fits are also an expression. The voice sign persists at least several years, even in the absence of fits, showing perhaps that even a prolonged absence of fits in epilepsy does not really indicate that a cure has been accomplished. The diagnostic and prognostic value of the epileptic voice sign is obvious.

5. A Case of Leprosy Apparently Cured with the X Rays.—Heiser reports a case of leprosy in a Filipino, twenty years of age. Treatment was begun November 5, 1906, from which date his lesions were exposed every third day to x rays for ten minutes at a distance of 25 centimetres from the tube. The intensity of the light employed was just sufficient to give a distinct outline of the bones of the hand. The regular Gundlach tube and a 45 cm. spark induction coil and a mercury turbine interrupter were used. From November 21, 1906, to January 21, 1907, the treatment was the same with the exception that his head was placed within 18 cm. of the tube. During this period he commenced to show considerable improvement, in that the lesions, most noticeable in the right ear, were rapidly growing smaller. From January 21st to February

8th he was exposed at a distance of 12 cm. from the tube. From February 8th to February 26th he was exposed every two days at a distance of 12 cm., from February 26, 1907, to July 1, 1908, every two days at a distance of 25 cm. for ten minutes. During June, 1907, the affected parts presented almost a normal appearance. The lepra bacillus was difficult to demonstrate, and many specimens were often necessary in order to find it. During January, 1908, the patient was apparently cured from a general clinical standpoint, the infiltrations had entirely disappeared, there were no anæsthetic areas, the ears were normal in size, and the cosmetic effect was practically perfect, so far as the leprosy was concerned. No lepra bacilli could be demonstrated at the site of the leprous lesions at which they had heretofore been found, but they could be found in scrapings made from the nasal sæptum. Shortly before this period, vaws made its appearance among the inmates of the Leper Hospital, and he also contracted this disease soon afterwards. Between January and June, 1908, repeated microscopical examinations were made, and lepra bacilli could be found only in specimens taken from the sæptum of the nose, and during the latter part of this period, it became more and more difficult to find them even there. From June 15, 1908, to August 1, 1908, the date of the last observation, it has been impossible to find lepra bacilli in specimens taken from any portion of his body.

Enlargement of the Spleen.—Osler groups splenic enlargements as follows: 1. In children

disturbances of metabolism and in chronic intestinal affections rickets, amyloid disease, and in a large but ill defined group of intestinal disorders, particularly in the tropics; the pseudoleuchæmia infantum. 2. In the infections, syphilis, malaria, kala azar, and other forms of tropical splenomegaly, Hodgkin's disease and tuberculosis. 3. In primary disorders of the blood forming organs, leuchæmia, pernicious anæmia, chlorosis (hæmochromatosis; polycythæmic splenomegaly. 4. In cirrhosis of the liver, syphilitic, alcoholic, hypertrophic of Hanot. 5. Hereditary and family forms of splenomegaly: (a) with the congenital acholuric icterus; (b) with constitutional disturbances, dwarfing, etc. 6. New growths and parasites: Sarcoma, primitive endothelioma of Gancher, echinococcus, and the schistosoma of Japan. 7. Splenomegaly not correlated with any of the above or with any known cause, Banti's disease with its three stages of (a) simple enlargement, (b) splenomegaly with anæmia, (c) splenomegaly with anæmia, jaundice, and ascites. It is in this last group that the writer is especially interested. Among its chief characteristics are the following: I. An extraordinary chronicity. The spleen may be enlarged for fifteen or twenty-five years, with but little disturbance of health at first. 2. The large size of the spleen; only in leuchæmia does the organ reach a larger volume. There is no correspondence between the size of the spleen and the symptoms. 3. The blood picture, which is that of a secondary anæmia. 4. Jaundice and ascites. occur as a result of cirrhosis of the liver. Hæmorrhages; these are common. 6. Pathology. The three important changes met with in the spleen are chronic fibrous hyperplasia, an enormous proliferation of the endothelial cells of the spleen sinuses, and lastly alterations (sclerosis, thrombosis, and stenosis) in the splenic veins and in the portal system. There is no clue to the nature of the disease; it is probably a chronic infective process with its chief seat in the spleen.

8. Fatty Acid Intoxication.—Guthrie's conclusions are as follows: Acidosis or fatty acid intoxication may occur in all cases in which the liver is excessively fatty. Acetone bodies being chiefly formed from fat, it is reasonable to suppose that their origin in these cases is in the fat in the liver and in the tissues. Although a normal liver is able to deal with enormous quantities of fat in its cells, a liver whose functions are deranged may not be able to do so. A liver may become superfatted as the result of: (a) Excessive supply of fats and carbohydrates in the diet. (b) Inability to metabolise fat supplied, or to make use of carbohydrates -glycogenic disorder (as in cyclical vomiting?). (c) Deprivation of carbohydrates (starvation). (d) As the result of sepsis, acute or chronic, or the action of specific organisms; for example, in gastrointestinal affections, or diphtheria, or pneumonia. (e) As the result of poisoning by phloridzin, hydrazin, phosphorus, chloroform. (f) The existence of a superfatted liver in itself is probably not dangerous. But it implies defective metabolism and oxidation as a rule. Should metabolism and oxidation be further perverted by the action of a general anæsthetic, fatal toxæmia, not attributable to fattv acid intoxication alone, but to a general breakdown

of all the hepatic functions-proteolytic, antitoxic, and glycogenic-may occur, and in extreme cases necrobiosis of the hepatic cells (acute atrophy) may result. (g) These results are not due to the specific action of chloroform alone, but may be the consequence of administering any general anæsthetic in the presence of a fatty and disordered liver. At the same time chloroform in these conditions is the most dangerous anæsthetic of all. (h) In cases of preceding hepatic inadequacy, the administration of any general anæsthetic may prove the "last straw." (i) Treatment by alkalies or carbohydrates affords but slender hope of cure in postanæsthetic intoxication. (j) Prophylaxis. Subjects of cyclical vomiting, perhaps those especially who live chiefly on fat and carbohydrates, are potential victims to postanæsthetic intoxication. The danger is probably least toward the end, and greatest on the eve of an attack of periodical vomiting. Anæsthetics may be dangerous in cases of acute and chronic sepsis, whether due to specific organisms or intestinal saprophytes. All these conditions are likely to be associated with fatty liver and consequent acidosis with possible inadequacy of hepatic function in general. It is extremely doubtful if fatty acid intoxication is ever the sole cause of death. Whenever there is reason to suspect the existence of fatty liver and possible hepatic inadequacy to deal with fat and carbohydrates, ether with oxygen would perhaps be the least dangerous form of anæsthetic to use.

Motoring Notes,
By C. T. W. Hirsch. Motoring Notes,

2. Blood Pressure.—Brunton, after describing the various instruments used to determine blood pressure in man, discusses the significance and regulation of high and low pressures. In man the average normal difference between the systolic and diastolic pressure is from twenty-five to forty millimetres of mercury. Both maximum or systolic blood pressure and its relationship to the diastolic pressure may undergo considerable variations in the same person. The maximum pressure in children from eight to fourteen years of age is about ninety millimetres; from fifteen to twenty-one years it is about 100 to 120; from twenty-one to sixty-five years of age from 120 to 135 or 150; and above sixty-five years of age it may still remain at 135 if the arteries are still elastic, or it may go up to 180, 200, or even higher. In women the pressure is, as a rule, about ten or fifteen centimetres lower

than the corresponding pressure in men. Attention is directed to an abnormally low blood pressure as a possible premonitory symptom of pulmonary tuberculosis. The blood pressure is apt to fall much below the normal in cases of general debility from overwork, underfeeding, and especially from acute disease. After influenza the fall is sometimes very notable. In cases of low pressure we use abundant food, especially animal food, meat extracts, strong soups, gentle exercise, with plenty of open air and sunshine. General tonics, such as iron, arsenic, malt, etc., are useful; also such cardiac tonics as digitalis, strychnine, and caffeine. In lowered tension the symptoms usually distinctly call for tonic treatment; but in cases of raised tension the high pressure within the bloodvessels frequently gives rise to a sense of power and a desire for action. High tension is not only a direct cause of cardiac failure or ruptured vessels in itself; it also produces atheroma of the arteries, and by thus weakening them renders them more liable to break. Rupture of elastic fibres is probably the primary cause of arteriosclerosis or arteriocapillary fibrosis and of atheroma. In arteriosclerosis the fractures are single, separate, and general; in atheroma they are multiple and aggregate. This would explain the patchy nature of the disease, those parts of the arterial wall being the first to suffer where the stress is greatest or where they are least protected. The substances which tend to raise the arterial tension during advanced life are unknown, but it is probable that some products of internal secretion and tissue metabolism tend to cause contraction of the vessels with rise of blood pressure. In addition it is quite possible that the products formed from an albuminous diet during digestion in the intestine may have a similar effect. The first indication in treating rise of tension is therefore to diminish the supply of proteid food, especially meat, and to substitute a diet of bread, vegetables, and fruit, with milk, butter, and fat bacon. Eggs, fish, and fowl may be allowed if the tension is not excessively high. Alcohol, tea, and coffee should be used sparingly, if at all. The same is true of tobacco, which produces atheroma per se in animals. Moderate exercise is beneficial, but sudden exertion should be avoided. The same is true of mental work. Constipation must be carefully avoided, as it tends to raise the blood pressume. Mercurials seem to have a specially beneficial action. Cases of high tension with failing cardiac action call for cardiac tonics combined with vascular dilators. In angina morphine has sometimes to be given.

5. Examination of Urine.-Weiss describes some of the modern methods for the examination of urine and the gastric juice, which are suitable for the use of the general practitioner. Among them may be mentioned the albuminometer of Harrower, which consists of a graduated tube, and the following reagent: Phosphotungstic acid, grammes; concentrated hydrochloric acid, grammes; and 95 per cent. alcohol, 100 cubic centimetres. One cubic centimetre of urine is diluted with nine cubic centimetres of distilled water, and this is added drop by drop to the reagent, shaking after each addition until the appearance of a faint

This denotes the completion of the white cloud. reaction and the level of the fluid in the tube is read off, it corresponding to the amount of diluted urine which contains one tenth of a milligramme of albu-The latest and best saccharometer is a graduated U tube in which evolution of carbon dioxide by fermentation causes displacement of a column of mercury. The amount of uric acid may be conveniently determined by means of Ruhemann's The principle involved is the fixation of free iodine by uric acid. The apparatus consists of a graduated tube and two reagents; a iodoiodide solution, similar to Gram's solution; and carbon bisulphide. The latter is poured into the tube up to a certain mark. The iodine solution is added to a further mark. Diluted urine is then slowly added until the carbon bisulphide, which from a deep violet hue acquired on the first addition of urine, passes through various depths of pink, and finally becomes snow white. This indicates the completion of the reaction, and the level of the mixture in the tube, read off on a graduated scale, gives the amount of uric acid present. Another simple instrument is the phosphatometer, with which the amount of phosphates is determined. The reagent precipitates the phosphates, which are read off on the scale. The reagent consists of magnesium chloride, five grammes; ammonium chloride, seven grammes; strong solution of ammonia, thirty-five grammes; and distilled water, sixty-five grammes.

Paralytic Accidents in the Course of Antirabic Treat-

By P. REMLINGER. Hypertrophy of the Thymus and Thyreoidectomy in Exophthalmic Goître, By R. ROMME.

2. Paralytic Accidents in the Course of Antirabic Treatment.—Remlinger reports two cases. in one of which the treatment for rabies was followed by paralysis and anæthesia of the lower limbs, in the other by paresis of the lower limbs. In both the paralysis was transient. The author discusses the cause, but as autopsies in such conditions must necessarily be infrequent owing to the transient nature of the accidents, not much can be determined as yet in regard to it.

Amylolytic Power of the Gastric Contents and Intestinal Digestion, By LEON MEUNIER. Muscular Physiology. Gymnastics of the Hip, By P. Desposses.

1. Amylolytic Power of the Gastric Contents. -Meunier has studied this subject in forty-five patients, testing with Ewald's breakfast, and finds that the gastric digestion of starch varies from 0 to 200. This variation he ascribes to two causes, insufficiency of the secretion of saliva and the acidity of the gastric juice.

2. Gymnastics of the Hip.—Desfosses gives in detail, with numerous illustrations, the movements of the femur in the hip joint, which, in spite of their multiplicity, are classed in three groups, 1, flexion and extension; 2, rotation inward and outward; 3, abduction and adduction.

megaly,
Concerning Bechterew's Flexor Reflex of the Toes,
By M. P. Nikitin.
Kernig's Symptom in Tetanus,
The Treatment of Gout,
By FALKENSTEIN.

1. Rupture of the Liver.—Chiari reports the case of a man who was under treatment for about three weeks with the clinical diagnosis of contusion of the right kidney, hæmothorax on the left side, and possible injury to the pancreas. Autopsy showed that there had been a total rupture of the left lobe of the liver, which was in the process of spontaneous healing.

4. Chemical and Histological Studies of the Blood in Acromegaly.—Franchini says that in acromegaly changes in the blood, especially in the leucocytes, are to be found frequently, even if not in all cases, and that there are also chemical changes in the composition of the blood, particularly a certain degree of lipæmia, and in general an increase of the mineral constituents, but he is unwilling to say that this fact is constant.

Acholuric Icterus with Splenomegaly. -Möller ascribes the ætiology of the clinical picture to a chronically acting noxious substance seated in the digestive tract and acting at the same time upon the blood and the liver.

6. Bechterew's Flexor Reflex .- Nikitin found in an examination of thirty-five cases of spastic paralysis both Babinski's and Bechterew's reflexes present in 57.1 per cent., Babinski's alone in 25.7 per cent., Bechterew's alone in 11.4 per cent., and both reflexes absent in 5.7 per cent. In seventeen cases in which both reflexes were present Bechterew's was present on one side only in six, a result that contradicts K. Mendel's statement that in parapareses this reflex always occurs on both sides. The cases in which Bechterew's reflex was positive, in spite of the absence of Babinski's, are of special

7. Kernig's Symptom in Tetanus.—Rostowzew reports five cases of tetanus, in four of which Kernig's symptom, flexion contracture of the knee joint, was present and well marked. He says that the literature on the subject of Kernig's symptom is too scanty to justify any conclusions, but that his observations leave no doubt that it is a constant and early symptom in tetanus. He does not consider that it can be used as a basis for a distinctive diagnosis between cerebrospinal meningitis and tetanus.

Study of Physicians,

By R. Beneke. By R. BENEKE.

- Traumatic Inflammation of the Joints.-König says that it has been shown both by experiments on animals and clinically that in the great majority of cases traumatic tuberculosis develops immediately after the receipt of the traumatism. The clinical course of these cases teaches us that as a rule it has begun within the first fourteen days after the injury. But we may extend the limit of the time during which it may appear with probability of a connection between the two to two months, and even three when it is taken into account that many forms develop very slowly before the presence of the disease is noticed. But it must be shown in all these late appearing cases that pathological symptoms, such as pain, swelling, or disturbance of function, were present from the time of injury to that of the detection of the disease in order to establish the probability of the dependence of the disease on the injury. If such symptoms are not present he does not believe the disease to be due to the accident.
- 2. Clinical Signification of the Determination of Antitrypsin in the Blood.-Von Bergmann and Meyer consider the estimation of the antitrypsin in the blood to be valuable clinically as a control to the clinical diagnosis of carcinoma.

6. Kernig's Symptom in Tetanus.-Rostowzew concludes that Kernig's symptom is one of the early and also one of the late symptoms in tetanus.

Concerning Measurement and Dosage of X Rays in Absolute Units, Prostitution and Its Regulation, By Kopp.

1. A New Method for Testing the Function of the Stomach.—Schläpfer, after a description of Sahli's test, says that by the introduction of a broth containing a neutral red as a staining material into the stomach it is possible first to determine from the staining of the urine the first emptying of the pylorus and the entire motility of the stomach, and, second to ascertain in a simple manner the propor-

tionate quantity of broth and gastric juice in the fluid siphoned from the stomach, and thereby the motor and secretory function of the latter. By its union with albumin, carbohydrates, and fat the broth forms an adequate physiological stimulant. By the staining of the filtered gastric juice its peptic power may be approximately ascertained, and from the change in color in the siphoned fluid from red to yellow or the reverse, the quantity of acid and the presence and intensity of fermentation can be de-

- 2. Bad Effects of Apomorphine.—Harnack reports the effects produced on himself by a dose of apomorphine administered subcutaneously. It induced severe vomiting, associated during the final act with intense muscular relaxation, such that he had to lie for about half an hour unable to lift a finger or summon aid. He questions whether this muscular paralysis was not the result of the act of vomiting.
- 3. The Ophthalmoreaction of Tuberculosis .--Wiens and Günther, after a detailed account of their experiments, declare that they consider the use of the ophthalmoreaction in practice to be injudicious because on the one hand it gives no positive results and on the other the possibility of a serious reaction can never be excluded.
- 7. Mastopexia for Pendulous Breasts.-Dehner excised a large ellipse of skin and subcutaneous cellular tissue at the upper periphery of the mamma down to the fascia of the pectoralis major. Then he split the fibres of the pectoralis major and minor, elevated the periosteum of the third rib, passed three strong sutures of catgut deep through the gland, and fastened them to the periosteal flap. Finally he closed the first wound with sutures. The result in his case was very good.
- 8. Acute Nonpurulent Thyreoiditis.—Dunger reports seven cases. Two were preceded by influenza with a slight bronchial catarrh, one by a dry pleuritis, one by a circumscribed pneumonia, both of the latter probably originating in influenza, two by catarrh at the apex of the lungs. In the remaining case the only associated disease was an ulcer of the stomach, which could not be shown to be the cause, so in this case he thinks the thyreoiditis was
- 10. Isolated Cross Laceration of the Mesentery in Contusion of the Abdomen.-Reinecke reports a case in which laparotomy, after a severe contusion of the abdomen, revealed an extensive tear of the mesentery as the only resultant injury. Gangrene of the ileum had commenced as a result of the laceration of the nutrient vessels.

By Krauss. Africa. Palliative Trephining in Choked Disc .-Von Hippel says that the palliative trephining of the skull in intracranial diseases that do not permit of a radical operation is an operation of interest, because belonging to the borderland of their specialties, to the neurologist, the surgeon, the ophthal-

mologist, and the otologist. In this paper he deals with the subject from the standpoint of the ophthalmologist alone as a preventive of blindness as the result of the venous stasis in the nerve. It has long been known to neurologists and surgeons that a choked disc will retrograde not only after the removal of an intracranial focus of disease, but after a simple opening of the skull. The statistics he gives are that of 221 patients fifty-three died after the operation, of the remaining 168 the choked disc retrograded in 100, did not retrograde in eighteen, and no statements were made in regard to this matter in the reports of the others. He concludes that the prognosis for the vision is favorable when the

favorable, if not absolutely bad, when at the time of the operation the vision has fallen so low as to be practically useless or is lost. It should not be concealed that the operation is not without danger

patient is operated upon in a relatively early stage,

that is while useful vision still exists, but is un-

although it is one we are justified in recommending because without it blindness is almost always unavoidable, while with it performed at the proper

time the prognosis is good.

Method for the Demonstration of Pigments and Their Colorless Stages. - Schreiber and Schneider describe the staining method employed, and thus sum up the results they have obtained in this manner: I, The chromatophore stroma cells of the iris possess besides the pigment holding processes of protoplasm other colorless processes the demonstration of which escapes the usual examination. 2. The silver impregnation procedure enables one to follow embryologically the distinction of the colorless young forms of the chromatophore stroma cells from the mesenchyme cells of the uvea. 3, The albinotic eye shows neither in the stroma cells of the uvea nor in the so called pigment epithelial layer of the retina a tendency toward the formation of pigment. 4, The Ribbert-Schieck theory that the weakly pigmented sarcoma is a young form of the melanosarcoma finds no positive confirmation through this method. 5, Langerhans's cells of the skin are probably nonpigmented melanoblasts. The cells of the nævus nests show no tendency to the formation of pigment.

5. An Apparently Unrecognized Disease of the Bones of Children.-Köhler describes three cases in which the os naviculare was found by the x rays to be very materially changed in size, form, structure, and proportion of lime salts. The ætiology is uncertain.

9. Treatment of Hay Fever .- Friedländer reports a case of hay fever in which quiet and deep respiration were secured by means of hypnosis.

12. The Prolonged Use and Toxic Action of Sulphonal,

By J. E. FALLEY. 1. A Clinical Study of some Arrhythmias of

the Heart.—James notes the great importance which is attached to the anatomy and physiology of the atrioventricular bundle of His. Much attention has also been paid to the study of the extra systole. The author narrates in detail the histories of two cases which show three distinct abnormalities of the atrioventricular bundle: (1) A destructive lesion of the bundle at the node; (2) an abnormal irritability or rhythmicity at the node; (3) a similar abnormal rhythmicity at the sinoauricular junction. The conclusions from the study of these cases are: (1) That complete heart block, going on to a fatal termination, is possible without the Stokes-Adams syndrome at any time. (2) That complete Stokes-Adams syndrome may exist in the presence of perfect atrioventricular conduction, an example of which has been mentioned by Lepine. (3) That there is another and closely allied syndrome, consisting of tachycardia in the presence of mitral and tricuspid regurgitation, associated with syncopal and epileptiform seizures. The physiological end result of these conditions is the same as in the Stokes-Adams syndrome, many systoles being lost by inability to open the aortic valves, while the physiological origin is entirely different, being in the one case hyperrhythmicity of the atrioventricular bundle and in the other a blocking of this structure.

3. Physical Therapeutics .- McKenzie includes in exercise as a therapeutic agent all means by which the body may be acted upon by movements, active or passive, performed by the patient himself,

by the hand of an operator, or by a suitable machine. It may be active or passive, the former including exercises of effort and those of endurance. The former include mainly those which are practised in early life, the latter those of middle life and old age. The active also includes duplicate movements, in which the dosage is measured by the hand of the operator or by the weighted lever of a machine. Such movements have as advantages accuracy, the power of isolating groups of muscles, and ability to stretch contracted parts. In passive movements the will power is not exerted and the circulation in the muscle itself is improved mechanically. application of exercise to pathological conditions of posture, of nutrition, of the circulation, and of the nervous system, success must depend upon the careful selection and accuracy of the kind of dose employed, and on persistence in following out a course of treatment. It is the neglect of these considerations which is responsible for most of the failures in its application.

4. The Present Status of Serum and Vaccine Therapy.—Richardson states that, contrary to early hopes, the great mass of bacterial disease still remains outside the antitoxine category, and that speculation has been forced to seek other theories to explain the immunity acquired after infection with organisms such as typhoid and kindred bacilli, the cholera spirillum, and the various cocci. In the fight against these specific organisms it has been determined that Nature's efforts are against the bacteria themselves and not against their toxines. now have good evidence that organisms such as typhoid, dysentery, or plague can produce soluble poisons, and that antitoxines of a moderate strength can be obtained. Studies in immunity have not only included bacteria and their infections, but a great variety of animal and vegetable cells and poisons, with their corresponding antibodies. These are considered successively, and the results which have been accomplished by them. With reference to the value of the opsonic index as a guide for the use of vaccines the author thinks the opinion has steadily gained ground that the index is so unreliable as not to justify the amount of time and trouble necessary for its determination.

The Paravertebral Triangle of Dulness (Grocco's Sign) in Pregnancy.—Smithies states that Grocco and others have demonstrated satisfactorily that when there is a collection of fluid in one pleural sac dulness may be determined by percussion on the opposite side of the spine. This dulness is roughly triangular in outline, the spinal column forming its vertical side. Paravertebral dulness is also obtainable in conditions other than simple collections of fluid in the pleural sac. Such is the case in lobar pneumonia when the consolidation lies near the spine, and with various new growths which involve the tissues of the mediastinum. The triangular form is less distinct with the latter than with pleural effusion. Paravertebral dulness is also obtainable in various conditions which are extra thoracic, and among them the author mentions pregnancy. Of the six cases reported, five were pregnant between the eighth and tenth months, and one at the sixth month. The dull areas along the spine were roughly triangular, with a hypothenuse which was more or less convex, and all were to the left of the midvertebral line. The dulness is due to the abdominal tumor which displaces other viscera upwards.

6. The Effect of Overcivilization on Maternity. Newell thinks that the conditions of modern civilized life have developed a type of woman abnormal with reference to the fulfillment of the function of pregnancy. The woman in humble life, foreign or native, who may have had privations and hard work, goes through her pregnancy without trouble, and though labor be severe she reacts well and is soon able to resume her ordinary duties. The overcivilized woman receives care and attention during her entire pregnancy, and if she survives labor it is with nerves weakened, and only after a long convalescence can she go about again. She seldom nurses her child, or nurses it but a few months. If it is thought a patient will bear labor badly, it should be brought on and terminated without reference to the period as soon as any unfavorable signs are apparent. An elective Cæsarean section will in some instances prove to be the wise procedure, even though there may be no pelvic obstruction.

Proceedings of Societies.

SIXTH INTERNATIONAL CONGRESS ON TUBER-CULOSIS.

Held in Washington, D. C., September 28, 29, and 30, and October 1, 2, and 3, 1908.

(Continued from page 864.)

Rest of the Lung in Pulmonary Tuberculosis. -Dr. Norman Bridge, of Los Angeles, Cal., said' that a tuberculous lung should be kept as still as possible, especially when the disease was unilateral. It was the universal custom to keep other tuberculous organs at rest. Immobilizing the lung relieved the symptoms and helped toward recovery. Reliable statistics upon this question were difficult to obtain; it would require at least 1,200 patients under constant observation by a careful and judicially minded observer for at least two years before any satisfactory conclusion could be made. from analogy and opinion, there was no reason for keeping a tuberculous joint still that did not apply to a tuberculous lung. Violence to a wound increased scar tissue; why not also in a fibrosis of the lung? Violent coughing and lung gymnastics might disseminate the disease. Stretching of the diseased tissue was apt to injure it. Gymnastics and violent coughing really stretched the nontuberculous tissue more than it did the tuberculous. The best thing was to give the patient fresh outdoor air to breathe. The Bier method of passive congestion doubtless tended to retard the disease and to help toward recovery. It was more effective in a lung that was kept still, because there was more passive congestion in such a lung. Artificial immobilization in a case of unilateral pulmonary tuberculosis always seemed to help the lung toward recovery, as did also the effusion of serum into the pleural cavity. Cough was harmful, and it was not important to expel mucus from the brouchial tubes, on that

account. Pus was not absorbed readily from the bronchi, and so did very little harm; therefore, in such a condition it was useful to suppress cough by the power of the will or by mild drugs.

The Ultimate Results of Sanatorium Treatment.—Dr. LAWRASON BROWN, of Saranac Lake, N. Y., said that his paper was based upon a study of the patients after they had left the sanatorium of which he was one of the physicians. The cases studied had been away from the influences of the sanatorium for periods varying from one to twentythree years. Of the first 300 patients discharged from the Adirondack Cottage Sanatorium, thirtysix per cent. were untraced; of the last 2,400 patients discharged, ten per cent. were untraced. Out of 2,553 patients discharged, 1,209 were known to be living. Of these, 1,058, or 87.5 per cent., were engaged in or were able to do some work. corresponded to forty-one per cent. of the total number discharged. Sixty-three of the patients who went to make up the statistics of the paper were discharged from fifteen to twenty-three years ago. The results were considered encouraging.

SECTION III.

(Continued from page 609.)

Tuberculosis of the Cervical Lymph Nodes. Report of Two Hundred and Seventy-Five Cases Treated by Radical Extirpation.—Dr. CHARLES H. Dowd, of New York, said that tuberculosis of the cervical lymph nodes was serious, and that the mortality rate of untreated cases was little below fifty per cent. On the other hand, when a thorough operation was done the death rate was about one third of one per cent. In eighty per cent. of cases the operation was followed by cure, and in ten per cent. there was improvement. As a result of a study of cultures made from the nodes in twenty cases he concluded that cervical lymph node tuberculosis was of both human and bovine origin.

Retroperitoneal Tuberculous Glands and their Relation to Spinal Symptoms (Tabes Mesenterica.) - Dr. CHARLES F. PAINTER, of Boston, said that there were many intraabdominal and intrathoracic conditions which would confuse the diagnosis of tuberculosis of the vertebral column. Tuberculous mesenteric and retroperitoneal lymph nodes were the most common of these. The infection of these structures from the intestinal canal was very easy. He discussed the ætiology, the pathological conditions in the infected nodes, and the results of necropsies; the value of the anamnesis, the methods of physical diagnosis, and the use of the x rays. He enumerated the various conditions which resembled tuberculosis of the intraabdominal lymph nodes, and gave the signs that enabled one to form an opinion. He divided the treatment into hygienic, operative, and mechanical.

The Surgical Aspects of Tuberculosis of the Lungs and Pleura.—Dr. Samuel Robinson, of Boston, said that little or no credit could be claimed by surgery for progress in the cure and prevention of tuberculosis. Not only was the history of intrathoracic surgery characterized by slower progress than the surgery of any other region of the body, but of lesions within the chest, those of a tuberculous nature had been especially unyielding to

surgical interference, and had given no encouragement to operators to invade that region. The literature supplied us with a discouraging story of tuberculous cavities drained by thoracotomy, in which the condition of the patient was temporarily relieved, although the course of the disease was not arrested. There were a few reported cases of partial or complete pneumectomy, in which the patient's life was shortened either by the shock of the operation, by the production of pneumothorax, or by the collapse of the opposite lung on account of injury to the mediastinum. In the few cases in which the operation could be regarded as successful, death was due to the increase and the spread of the disease from the remaining lobes of the side operated upon and to the transmission of the infectious material to the opposite lung. The twentieth century hadalready witnessed an advance in the technique of intrathoracic surgery by the introduction of the negative pressure method of avoiding the dangers of pneumothorax, and also by the perfecting of the positive pressure method of obviating these dangers. The investigations of Sauerbruch, Brauer, Matas, Smythe, Greene, Janeway, Mayer, Tuffier, Seidel, and the author had proved that an exploratory thoracotomy was attended, under the new methods, by no greater danger than an exploratory laparotomy. The investigators mentioned also agreed that the partial or complete removal of one or two lobes of either lung was an operation which could be regarded as attended with little danger to the patient. The latter conclusion was based largely on animal experimentation, but it was a well known fact that the human thorax was less prone to infection and less susceptible to the dangers of pneumothorax than that of most animals which had been used in experimentation. The human mediastinum being a comparatively unvielding structure, the conditions of the unopened side of the thorax were not so unfavorable as in the dog. Granted, however, this newly justified procedure of thoracotomy for exploration or partial pneumectomy, what could be said as to the prospects of successful surgical attack on pulmonary tuberculosis? An insufficient number of patients had been operated upon since the perfection of the new methods from which to draw any conclusions. It was to be regretted, however, that the cases most suited to operative interference were also the ones commonly recognized as most promising for hygienic results; namely, those cases of isolated foci confined to one or two lobes of one lung. With the help of the x rays such cases were early recognized, even before physical signs were present, but the physician would hesitate to turn such a case over to the surgeon for lobe excision until he had resorted to general treatment. Having failed in the latter, the patient would then be a far less suitable subject for the total excision of the diseased area, owing to the extension of the infection, to the involvement of other lobes, and even to the direct transmission of infective material to the opposite lung. In other words, it could no longer be justly stated that tuberculosis of the lung and pleura was out of reach of the surgeon, but the question remained an open one as to whether drainage or excision of tuberculous foci in the thoracic cavity could ever result in the removal of the infection. It was at least to be hoped

that the disease might be more successfully attacked by "vaccine" therapy and hygiene if the larger cavities of infective material had meanwhile been excised or drained by the surgeon.

Section I. Pathology and Bacteriology. (Continued from page 810.)

IMMUNITY.

The Problem of Immunity in Tuberculosis.-Dr. Edward R. Baldwin, of Saranac Lake, N. Y., said that as a whole the results of the attempts to produce active immunity to the tubercle bacillus and its products were discouraging. Attention was then turned to the attempt to produce an antitoxic immunity. As a result of that work, soluble extractives of tubercle bacilli, emulsions, and new tuberculins were introduced with some success. The discovery of the differences in the virulence of the human and the bovine types of the Bacillus tuberculosis gave a further impetus to the attempts to produce active immunity, and the study of various pseudotubercle bacilli, and of those modified by passage through reptilians, gave new hope of such a possibility. Further work, however, seemed to show that the goal was still as distant as it ever had been. Dr. Baldwin referred to the "bovovaccine" of von Behring, to the "tauruman" of Koch and Schütz, and to the "tulase" introduced at the Paris Congress in 1905. He referred also to the work of Pearson and Gilliland on the attempt to immunize cattle by spacing the inoculations at longer or shorter intervals; to the work of Calmette and Guérin by feeding the "vaccine"; to that of Heymanns by giving the bacilli in capsules; and to that of Klimmer by the use of bacilli which had been made nonvirulent or modified by passage through other species of animals. In spite of all these attempts, however, the situation was not hopeful. The specific resistance of cattle waned after one or two inoculations of human bacilli, and failed entirely after six months to two years. Furthermore, living human tubercle might be retained in the tissues or excreted in the milk of the protected cows for many months after the inoculations had been made. Subcutaneous injections, it had been maintained, gave equally strong protection to cattle as injection by the intravenous route. By this method, however, there was the danger of producing a local abscess. There was a subtle difference between the living and the dead tubercle bacilli as immunizing agents, and this difference needed to be studied. Thus far no method had appeared of equal value to the inoculation with the living bacilli. According to the present outlook, repeated protective treatment was necessary by an agent equally in-nocuous to cattle and to man. It appeared desirable that all avenues of infection should be subjected to local immunization-for example, by feeding and by inhaling the protective agent. The finer mechanism of immunity needed close study to adjust the doses and the intervals of administration; some way of measuring immunity was needed. A correct balance must be attained between the specific response to infection, which occurred during the supersensitive phase of immunity, and the ability of the tissues to assimilate the poisons without suffering harm. An immunity which tended merely to arrest the infection, but not to overcome it, was not wholly bene-

ficial when it created ulceration at the portal of entrance. Hence the question of the beneficence of supersensitiveness artificially induced by protective inoculations must be considered. An immunity without tuberculin susceptibility might be defective; on the other hand, complete tolerance to tuberculin might be associated with a high resistance to infection in cattle. The problem, then, seemed to be to create tolerance for the bacillus poisons, or its products when undergoing lysis, and their assimilation by the tissues. Without the unknown quality called tolerance no real immunity could exist; and the earlier in life this could be established with absolute safety the more resistant would the adult become. The studies of Bartel on the influences of lymphatic cells on the tubercle bacillus, as well as those of Opie on the leucocytes, promised to enlarge our knowledge of this subject. More light might come from the studies on anaphylaxis, now in progress, and the prevention of the phenomena attending it. Finally, the problem of passive immunity was still a distant goal which gave hope of the development of an efficient therapy.

(To be continued.)

Rew Inventions.

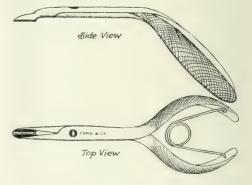

A SUBMUCOUS FORCEPS FOR REMOVING THE MAXILLARY RIDGE.

By A. J. Huey, M. D., New York,

Attending Laryngologist to the Clinic of the Health Department.

Among the difficulties encountered in the submucous resection of the nasal sæptum, none is more annoying than the removal of the maxillary ridge, often complicated by a bony spur near the floor of the nose. This has led me to devise the instrument shown in the cut.

The blades are in form like those of the rongeur bone forceps, the cutting edge being at the lower

edge of the blade. The instrument here presented has a very thin blade, so that it may be easily passed beneath a projecting spur. The bony maxillary ridge is cut away from the floor of the nose, when it may be broken with ease from its posterior attachment with a nasal forceps.

15 CENTRAL PARK WEST.

Book Motices.

[We publish full lists of books received, but we acknowledge no obligation to review them all. Nevertheless, so far as space permuts, we review those in which we think our readers are likely to be interested.]

Operative Midwifery. By J. M. Munro Kerr, M. B., C. M. (Glas.), Fellow of the Faculty of Physicians and Surgeons, Glasgow; Obstetric Physician, Glasgow Maternity Hospital, etc. With 294 Illustrations in the Text. New York: William Wood & Co., 1908. Pp. xi-705. (Price, \$6.)

This excellent work is much more comprehensive than its title indicates. It is not a mere exposition of obstetrical operations; it deals with the nature, ætiology, and diagnosis of those conditions which may call for operative intervention. Moreover, the author does not fall into the very common error of looking upon cutting operations alone as surgical; he recognizes that manipulation and the use of apparatus are also surgical. We are glad to see gentleness of procedure the dominant feature of the author's teaching. "It would appear," he says, "as if the accoucheur considered it a disgrace not to be able to accomplish delivery by forceps or by version, and so he has recourse to unjustifiable How adequately he looks upon a patient as a patient rather than as a corpus vile to be subjected to an operation appears from the following: "A steadily rising pulse rate is of most value, and must always be looked upon as a danger signal. The same applies to a steadily rising temperature and increasing restlessness."

As regards artificial rotation of the head in occipitoposterior positions, Dr. Kerr says: "The only manœuvre I have found of real service is rotating the head by means of the hand passed into the vagina." Though he is an advocate of the use of rubber gloves in general, he says: "Although in ordinary vaginal examinations and deliveries with forceps I have had no inconvenience from them, I have found that I could not obtain a satisfactory hold of the child's leg in version, for example, and that I could not grasp hold of portions of adherent membrane when these were retained in the uterus. Indeed, in these latter operations I have sometimes required to remove the gloves before I could carry out the manipulations necessary." He thinks it impossible to predict the ultimate place of symphysiotomy, but he says: "Personally, I believe the operation fills a most useful place in practice, and that is the opinion of many others, and if every one would deliberately struggle against taking up an extreme position with regard to the operation, that place could be more exactly determined.

British obstetricians do not now write so jauntily of craniotomy as they did fifty years ago, but our author seems to be somewhat under the influence of the old teaching. "As regards the ethical and legal aspects of the subject," he says, "I offer no opinion. There are no hard and fast ethical rules nor are there any definite laws on the subject. If the matter were put before a committee of representatives of the medical and legal professions and educated lay public, I feel certain the opinion would be given unhesitatingly that it is sometimes right to destroy a living child." We believe the profession is drawing to the opposite opinion, and this is the only point in Dr. Kerr's book that grates on us. His advice in general seems to us most judicious.

A brief appendix on pelvimetry by means of the Röntgen rays, by Mr. J. R. Riddell, of the Glasgow Royal Infirmary, is a novel feature, so far as we know, of a book on obstetrics. The book is handsome from the typographical point of view, and the illustrations are for the most part exceedingly satisfactory. The work ought to be studied by all general practitioners.

Das Ohrlabyrinth als Organ der mathematischen Sinne für Raum und Zeit. Von E. von Cyon. Mit 45 Textfiguren, 5 Tafeln, und dem Bildnis des Verfassers. Berlin: Julius Springer, 1908. Pp. 432. (Price, \$3.50.)

This is a fascinating monograph, dedicated to the spirit of three investigators who opened the path for the modern study of the nervous functions of the labyrinth, Flourens, Weber, and Vierordt. It opens with the experimental fouundations of space perception as made out by the investigations of Flourens on the semicircular canals of pigeons, and then passes in review the psychological theories con-

cerning space perception.

Cyon then takes up his own studies tending to demonstrate the functions of the auditory apparatus as an organ of space perception, finishing his third chapter with a discussion of labyrinthine tonus and the relations of the cerebellum to the semicircular canals. Chapter IV is taken up largely with a discussion of the Japanese dancing mouse in its relations to the general problem. Space orientation in vertebrates and invertebrates is then dwelt upon. Chapter V makes use of the pathological evidence, while Chapter VI gives a discussion of the physiological principles underlying the Euclidian geometry. This leads the author to his final chapter on time sense and consciousness of arithmetical relations, in which he reaches the conclusion of his general thesis that the labyrinthine apparatus is not only the organ of spatial perception, but also that of time.

Any short review fails to do justice to the masterly manner in which the problems involved are handled. That they have an important bearing in medicine is unquestioned, especially to the student of the modifications of memory, of equillibration, and of time approximations. The neurologist and the psychiatrist, as well as the aurist, will do welf to know this work.

Intestinal Autointoxication. By A. Combe, M. D., Professor of Clinical Pædiatry at the University of Lausanne, etc. Together with an Appendix on the Lactic Ferments, with Particular Reference to their Application in Intestinal Therapeutics, by Albert Fournier, formerly Demonstrator at la Sorbonne, Paris. Only Authorized English Adaptation. By WILLIAM GAYNOR STATES, M. D., Clinical Assistant, Rectal and Intestinal Diseases, New York Polyclinic, etc. With Eighteen Figures in the Text, Four of Which are Colored. New York: Rebman Company. Pp. xviii-461.

This is an important book and a very valuable one, bearing throughout upon the general practice of medicine, and the medical profession of the United States will feel indebted to Dr. States for having furnished a readable adaptation of it in English. About half the book is devoted to the toxic substances generated in the intestine, to the antitoxic functions of the organism, to experimental pathology in its bearings on the subject, to the causes of intestinal autointoxication, and to the symptomatology and diagnosis. The remainder deals with the treatment by diminishing nitrogenous

putrefaction and the vitality of proteolytic microbes, by the expulsion of those microbes and their toxic products, and by stimulating the action of the anti-

toxic organs and the emunctories.

Efficient intestinal antisepsis by means of drugs is declared to be impossible, and so we have always maintained. Nevertheless, something may be accomplished in this direction. Calomel is set down as an occasional antiseptic of the first order, also the use of castor oil within reasonable limits. A one per cent, solution of menthol, too, is held to be of great value, but the author omits to mention that menthol is almost insoluble in water. The theories of Metchnikoff and others with regard to the action of sour milk in its various forms on pathogenic germs in the intestine are duly expounded, and the therapeutic value of yeast, a remedy much neglected in this country, is well set forth.

A second edition ought to be called for before long, and we hope that the translator will then correct the numerous errors of expression that have crept into the book. Some of them are as follows: "Dycrasic" and "dycrasia" for dyscrasic and dyscrasia, "brenzcatechin" for pyrocatechin, "hydrochinon" for hydroquinone, "ileus" for ileum, "typhilitis" for typhilitis, "MacBurney" for McBurney, "Bulckley" for Bulkley, "empyæmia" for empyema, and "salycilic," etc., for salicylic, etc. These are not printer's errors, for most of them occur repeatedly. Moreover, we dislike to see "&" used instead of and to connect men's names; it looks too commercial. The frequent recurrence of "Maly's" in the footnotes will lead many a reader to ask, Maly's what?

The mechanical appearance of the book is exceedingly creditable to the publishers, and we would particularly commend the tinted cuts.

BOOKS, PAMPHLETS, ETC., RECEIVED

Obstetrics for Nurses. By Joseph B. De Lee, A. M., M. D., Professor of Obstetrics, Northwestern University Medical School; Obstetrician to Mercy, Wesley, Provident, Cook County, and Chicago Lying-in Hospitals, etc. Third Edition. Thoroughly Revised and Enlarged. Philadelphia and London: W. B. Saunders Company, 1908. Pp. 512. (Price, \$2.50.)

American National Red Cross Textbook on First Aid and Relief Columns. A Manual of Instruction. How to Prevent Accidents and What to do for Injuries and Emergencies. By Major Charles Lynch, Medical Corps, United States Army. Prepared for and Endorsed by the American National Red Cross. With Seventy-four Illustrations. Philadelphia: P. Blakiston's Sons & Co., 1908. Pp. viii-247.

The Origin of Vertebrates. By Walter Holbrook Gaskell, M. A., M. D. (Cantab.), LL. D. (Edin. and McGill Univ.); F. R. S.; Fellow of Trinity Hall and University Lecturer in Physiology, Cambridge, etc. London. New York, Bombay, and Calcutta: Longmans, Green, & Co., 1908. Pp. ix-537.

Lectures on Principles of Surgery. By Stuart McGuire, M. D., Professor of Principles of Surgery and Clinical Surgery, University College of Medicine, Richmond, Va. Baltimore: Southern Médical Publishing Company, 1908.

Pp. 480

Atlas der Syphilis und der venerischen Krankheiten mit einem Grundriss der Pathologie und Therapie derselben von Hofrat Professor Dr. Franz Mracek in Wien. Zweite vermehrte und verbesserte Auflage. Mit 81 farbigen Tafeln nach Original-Aquarellen von Maler A. Schmitson und 26 schwarzen Abbildungen. München: J. F. Lehmann, 1908. Pp. xii-218.

A Reference Handbook for Nurses. By Amanda K. Beck, Graduate of the Illinois Training School for Nurses. Second Edition, Revised. Philadelphia and London: W. B. Santskin Company, 1988 Pp. 1990. (Price, \$125.)

Miscellany.

Corrigenda.—In Dr. Nepper's article on Mucomembranous Enterocolitis, published in our issue for May 23d, the concluding paragraphs should read:

I. The false membrane is the result of increased coagulative power and diminished biliary secretion.

2. Mucomembranous enterocolitis is the result of insufficient biliary secretion.

In Dr. Beverley Robinson's article on the Treatment of Acute Coryza, printed in our issue for October 31st, the formula at the top of page 844 should

 B
 Oleoresin of cubeb,
 m xx;

 Powd. camphor,
 gr. x;

 Glycerin,
 .3j;

 White petrolatum,
 .5ij.

Meir Remedies.

In order to satisfy a demand for information regarding the additions to our materia medica, the following notes on new remedies have been compiled from the various journals of medicine and pharmacy published in this country and in Europe. Modern chemical synthesis is constantly adding to the number of extrapharmacopacial remedies, and the sources of information regarding them are not readily accessible to practising physicians, being scattered through a mass of literature and entailing considerable research. It is intended to publish these notes regularly, and in this way keep the medical profession informed regarding remedies of recent introduction.

Cellasin is represented to be a carbohydrate and fat splitting ferment, which forms a brownish white, amorphous, odorless powder, soluble in water that has been rendered alkaline. It is said to be capable of decomposing 3000 times its weight of sugar or starch, and of emulsifying and decomposing fats in an alkaline medium. It is administered in doses of 2 to 14 grains thrice daily after meals, in disorders of nutrition, including diabetes and early tuberculosis.

Cheiroline is an alkaloid obtained from an extract of the wallflower, *Cheiranthus cheiri*, which is of special interest, owing to the fact that it is one of the few alkaloids containing sulphur in its molecule. It is soluble in alcohol, ether, and chloroform, but insoluble in water. It is said to have an antipyretic action, similar to quinine.

Cinerol is the name given to a mercurial oil used for the hypodermic treatment of syphilis, and consisting of mercury, 4 grammes; sterilized palm oil, 20 c.c.; sterilized sesame oil, 20 c.c. No directions are given for its manufacture, but the mercury is probably extinguished in the old fashioned way by assiduous rubbing with the palm oil, the sesame oil being added by degrees.

Decilan is a formaldehyde potassium oleate solution; in which part of the formaldehyde is combined as trioxymethylene. It forms a clear, yellow, alkaline liquid which mixes clearly with water, alcohol, and glycerin. It is recommended for use as an antiseptic and disinfectant.

Ennan, which is put up as a tablet weighing I gramme, is a combination of cresol with sodium stearate formed by the addition of alcohol, and containing free alkali. Each tablet contains 50 per cent.

of cresol. It is used as a surgical antiseptic, deodorant, and disinfectant.

Enterin Poehl is an organotherapeutic substance forming a yellowish brown powder, which dissolves in 100 parts of water to form a turbid solution. It is said to represent the synergistic group of the secretions contained in the duodenum and jejunum freed from toxines. It is recommended as a remedy in debilitated conditions of the pancreas and to increase the functional activity of Lieberkühn's and Brunners' glands.

Mercury Bromide Solution for the hypodermic administration of mercury consists of mercurous bromide, 1,8 grammes; sodium bromide, 1.4 grammes; distilled water, enough to make 100 c.c. It is in-

jected in doses of 1 to 2 c.c.

Noridal Suppositories, a remedy for hæmorrhoids, contain in each suppository the following ingredients: Calcium chloride, 0.05 gramme; calcium iodide, 0.01 gramme; paranephrin (adrenalin chloride), 0.0001 gramme; balsam of Peru, 0.01 gramme, with a vehicle of cacao butter, lanolin, and spermaceti.

Paratoxine is the name applied by two French physicians (Professor C. Lemoine and Professor E. Gerard, of Lille) to a mixture of cholesterin and biliary extract obtained from the bile of young oxen and pigs by extraction with petroleum ether boiling at 113° F. It forms a solid extract, which contains, besides cholesterin, lecithine, oily bodies, and traces of an undetermined nitrogenous substance precipitated by ether. Paratoxine is partly soluble in cold alcohol, very soluble in fixed and volatile oils, and in liquid petrolatim. It is recommended for use in the treatment of tuberculosis and is best given hypodermatically.

Perglutyl is a solid form of hydrogen dioxide. which is the subject of a German patent. It is made by dissolving gelatin in hydrogen dioxide solution by the aid of a gentle heat, and adding sufficient glycerin to yield a solid product when cooled. By varying the proportions of glycerin and gelatin varying melting points may be obtained. The perglutyls of the market melt between 77° and 104° F. It can, however, be made of such a consistency as to permit of its being powdered. It is used in all the indica-

tions in which hydrogen dioxide is used.

Phenolphthalein and Phenolphthaleinic Disodoquinone.-Phenolphthalein has a marked laxative and purgative effect in man, but produces no griping nor irritation of the gastrointestinal mucous membrane. The same is true of phenolphthaleinic disodoquinone, a soluble derivative which acts less strongly, and to which the name of sodophthalyl has been given. These substances, for some reason, act less energetically on animals. They are supposed to stimulate the hepatic, pancreatic, and intestinal secretion, and probably stimulate the intestines both directly and reflexly. Sodophthalyl may be given hypodermically, when its action is less marked, but on longer duration. The hydragogue action of phenolphthalein is so marked that it is spoken of as an "intestinal diuretic," and is said to be a powerful eliminating agent in toxic conditions.

Spirosal, the monoglycolester of salicylic acid, forms a nearly colorless and odorless liquid that is

easily soluble in alcohol, ether, chloroform, and benzol, as well as in 110 parts of water and in 8 parts of olive oil. It is miscible with an equal weight of petrolatum or lard. Undiluted it is used as an application for rheumatic pains, and as an embrocation in troublesome perspiration.

Public Health and Marine Hospital Service:

Official list of changes of stations and duties of commissioned and other officers of the public health and marine hospital service for the seven days ending October 21, 1908:

Billings, W. C., Passed Assistant Surgeon. Relieved from duty at Vancouver, British Columbia, and directed to proceed to Washington, D. C., for further orders.

proceed to Washington, D. C., for further orders.

Blanchard, J. F., Acting Assistant Surgeon. Granted two
days' leave of absence from October 22, 1908.

CARMICHAEL, D. A., Surgeon. Granted eighteen days' leave of absence from November 16, 1908.

COFER, L. E., Passed Assistant Surgeon. Relieved from

duty in the Hawaiian Islands and directed to proceed

to Washington, D. C., for further orders.

Grubbs, S. B., Passed Assistant Surgeon. Directed to proceed to St. Petersburg, Russia; Berlin, Germany; and Libau, Russia, on special temporary duty. Detailed to represent the Service at the meeting of the International Committee at Paris, November 4, 1908.

Heiser, V. G., Passed Assistant Surgeon. Detailed to represent the Service at the meeting of the Southern Medical Association at Atlanta, Ga., November 10 to

12, 1908.

LYALL, ROBERT, Acting Assistant Surgeon. Granted twelve days' extension of leave of absence, without pay, from

October 5, 1908.

RODMAN, J. C., Acting Assistant Surgeon. Granted ten days' leave of absence from October 15, 1908.

EDWARD, Pharmacist. Granted seven days' leave of absence from October 14, 1908, under paragraph 210, Service Regulations.

STIER, CARL, Pharmacist. Granted one month's leave of

absence from November 8, 1908.

STONER, J. B., Surgeon. Granted five days' leave of ab-

sence from October 19, 1908.

PPAN, J. W., Acting Assistant Surgeon. Directed to proceed to Eagle Pass, Laredo, and Brownsville, Tex., and Naco, Douglas, and Nogales, Ariz., on special temporary duty.

VILLOLDO. Pedro, Acting Assistant Surgeon. thirty days' leave of absence from October 20, 1908.

WHITE, M. J., Passed Assistant Surgeon. Granted seven days' leave of absence from October 16, 1908.
YOUNG, G. B. Surgeon. Directed to proceed to Port Huron, Mich., and Milwaukee, Wis., on special temporary duty.

Appointment.

John K. Thompson appointed a pharmacist of the third class.

Boards Convened.

Board of medical officers convened to meet at the Marine Hospital, Baltimore, Md., October 17, 1908, for the purpose of making a physical examination of cadets of the Revenue Cutter Service. Surgeon L. L. Williams, chairman; Passed Assistant Surgeon J.

ssistant Surgeon J. T. Burkhalter, recorder. Board of medical officers convened to meet at the Marine Hospital, New Orleans, La., upon the call of the chairman, for the purpose of reexamining a candidate for a position in the Life Saving Service. Surgeon J. H. White, chairman; Passed Assistant Surgeon H. W. Wickes, recorder.

Board of medical officers convened to meet at the Marine Hospital, Baltimore, Md., October 26, 1908, for the purpose of making a physical examination of cadet engineers of the Revenue Cutter Service for promotion. Surgeon L. L. Williams, chairman; Passed Assistant Surgeon J. T. Burkhalter, recorder.

Army Intelligence:

Official list of changes in the stations and duties of officers of the medical corps of the United States Army for

the week ending October 31, 1908:

BINGHAM, E. G., Captain, Medical Corps. Ordered to inspect Hospital Corps Detachments of the New York State National Guard in Buffalo, Rochester, and Bing-

hamton, N. Y. Grubbs, R. B., Captain, Medical Corps. Ordered from Fort McIntosh, Tex., to Fort Sam Houston, Tex., for

observation and treatment.

HASSELTINE, H. E., First Lieutenant, Medical Reserve Corps. Left Fort Thomas, Ky., on leave of absence

for two months.

HUBER, E. G., First Lieutenant, Medical Corps. Relieved from further duty with Company C, H. C., at the Genfrom turtner duty with Company C, H. C., at the General Hospital, Washington, D. C., and ordered to Fort Slocum, N. Y., for duty.

LYNCH, CHARLES, Major, Medical Corps. Ordered to inspect the Hospital Corps Detachments of the New York State National Guard in New York City.

QUINTON, W. W., Capitain, Medical Corps. Granted an extension of two months to his sick leave of absence.

RHOADS T. L. Capitain Medical Corps. Ordered to Wash-

RHOADS, T. L., Captain, Medical Corps. Ordered to Washington, D. C., for examination for promotion.

ROCKHILL, E. P., Captain, Medical Corps. Ordered to Denver, Col., for examination by an Army retiring board.

SANFORD, J. L., First Lieutenant, Medical Reserve Corps. Granted leave of absence for one month

STOCKARD, J. K., First Lieutenant, Medical Reserve Corps. Granted leave of absence for one month, about December 5th.

WHEATE, J. M., First Lieutenant, Medical Reserve Corps. Relieved from duty at Fort Yellowstone, Wyo., and ordered to Fort Lincoln, N. D., for duty.

Navy Intelligence:

Official list of changes in the stations and duties of officers of the medical corps of the United States Navy for the week ending October 31, 1908:

ELLIOTT, M. S., Surgeon. Detached from the Maine and ordered to the Naval Hospital, Washington, D. C. HUNGER, C. B., Assistant Surgeon. Detached from the Maine and ordered to the Naval Hospital, Portsmouth,

CORMICK, A. M. D. Surgeon. Detached from the Naval Recruiting Station, Baltimore, Md., and ordered to the Maine as Fleet Surgeon of the Third Squadron, McCormick, A. Atlantic Fleet.

Births, Marriages, and Deaths.

Born.

RICHARDS.—In Havana, Cuba, on Thursday, October 22d, to Captain Robert L. Richards, Medical Corps, United States Army, and Mrs. Richards, a son.

Married.

BAKER—Noble.—In Washington, D. C., on Saturday, October 24th, Dr. Chester A. Baker and Miss Adeline T.

BUSH-PHILLIPS.—In Armada, Michigan, on Wednesday, October 21st, Dr. Howard J. Bush and Miss Edith Phillips.

HIGGINS-MULVEY .- In Philadelphia, on Wednesday, October 28th, Dr. Joseph F. Higgins and Miss Mary Irene

TILLEY—ROBLIN.—In Syracuse, New York, on Tuesday, October 20th, Dr. Frank W. Tilley, of Washington, D. C., and Miss Bertha Irene Roblin.

Died.

BUCKLEY.—In Philadelphia, on Sunday, October 25th, Dr. William C. Buckley, aged seventy-five years.

CAFFEE.—In Carthage, Missouri, on Friday, October 23d,

Dr. A. H. Caffee

FENNEL.—In Cincinnati,, Ohio, on Friday, October 23d.

Dr. Otto Fennel, aged forty-seven years.

Graham.—In Batavia, N. Y., on Tuesday, October 27th,
Dr. Richard Fred Graham, aged thirty-one years.

HAWKINS.—In Bayou Chicot, Louisiana, on Thursday,

October 22d, Dr. J. E. Hawkins, aged seventy-one years.
HUTCHINS.—In Spokane, Washington, on Wednesda
October 28th, Dr. Edwin E. Hutchins. Washington, on Wednesday,

NICOLL—In New Windsor, New York, on Tuesday, October 27th, Dr. Henry D. Nicoll, aged sixty-four years.

Person.—In Lincoln, Nebraska, on Thursday, October

22d, Dr. Edward Person. PLYMPTON.—In Brooklyn, New York, on Thursday, October 29th, Dr. Harry Plympton, aged fifty years.

Scott.-In Germantown, Pennsylvania, on Saturday. October 24th, Dr. A. W. Scott, of Syracuse, New York, aged

fifty-seven years.
Tuttle.—In Hyde Park, Massachusetts, on Sunday, October 25th, Dr. Samuel Albert Tuttle, aged seventy-one

Voerster.—In St. Louis, Missouri, on Monday, October 26th, Dr. Engelbert Voerster, aged sixty-six years. WALSH.—In Milwaukec, Wisconsin, on Sunday, October 25th, Dr. Thomas Gregory Walsh, aged forty-seven

Wengenroth.—In Boston, on Thursday, October 22d., Dr. Adolphus Wengenroth, aged fifty-eight years. Williams.—In Denorwick, Canada, on Saturday, Octo-ber 24th, Dr. Wellington Williams, of Theresa, New York, aged forty years

THE RELATIONS OF THE PRIEST AND THE PHYSICIAN.

A Sermon Preached in the Memorial Church of the Good Shepherd, Rosemont, Pa., on St. Luke's Day, October 18, 1908.

By the Rector, the Rev. Arthur B. Conger.

Give place to the physician, for the Lord hath created him: let him not go from thee, for thou hast need of him. There is a time when in their hands there is good success. For they also shall pray unto the Lord, that He would prosper that which they give for ease and remedy to prolong life.—Ecclesiasticus xxxviii, 12-14.

O Lord, by these things men live, and in all these things is the life of my spirit; so wilt Thou recover me, and make me to live.—Isaiah xxxviii, 16.

Of St. Luke our positive information is slight, as is the case with most of the writers of Scripture; the reason being, strange as it may sound to modern ears, their purpose was to sink, not exploit, their own personality, that they might hold up the character of God to the affection and admiration of their readers and His truth to their contemplation But the most reliable indications and guidance. we possess seem to suggest that he was a freedman, what he himself would call one of the Libertini, born in Lucania, in Southern Italy, whence his name; that he completed his medical studies at the world renowned school of Tarsus, where he met St. Paul and "learned Christ." That he was highly educated need not be said to the reader of the Greek Testament, who has been fascinated by his polished sentences and struck by his clear distinctions and the accuracy of his historical knowl-

There can be little doubt that when St. Paul styles him "the beloved physician," he employs no empty phrase, but one which welled up from a very full heart and traced its source to a skill, fidelity, and tenderness which memory treasured with a firm and grateful tenacity. For we find that on each occasion when the "we" introduced into the narration apprizes us that the Evangelist has joined the Apostle, the latter was suffering extreme physical ill. When they met at Troas it was after St. Paul had been detained in Galatia by "the infirmity of his flesh." Again, when they met on the voyage to Jerusalem, St. Paul had had the "sentence of death in himself," had been dying daily, had been carrying about in his body the dying of the Lord Jesus. And the ministrations given with so much care and zeal and attended by results so beneficent that the

Apostle was enabled to continue his great work, to a man of his character and warmth of heart, won lasting affection and admiration almost unbounded.

Now, here, if you will permit me, I wish to find the fundamental relation of the priest to the physician. It is personal. It is founded upon appreciation of gifts and culture, of fidelity to duty, which, when necessary, is so self sacrificing as to border upon, if it does not often reach the heroic. If I may be pardoned for momentarily giving this sermon a personal note, I should like to grasp the opportunity to say that in my experience, and I wish to include in that what I have observed in the many and varied homes I visit. I have found no class of men who had the brains, knowledge, culture, and conscientious devotion to what appeared to them to be their duty, exhibited by physicians. And I should like to say a word for their most able coadjutors, the trained nurses. They differ, of course, like every other class taken from our imperfect humanity. But, on the whole, I do not believe that any other vocation develops in women equal sagacity, skill, and delicate manifestation of tact and sympathy. And while there are probably those who fail to appreciate them, I think they have the regard and in many cases real affection of the great majority of their worthy patients.

This is my first idea, then. "We honor" you, as

the lesson says, "for the uses we may have of you" and also for what you are in yourselves. Can we get any further than that? For instance, have you any use or uses for the priest? Dr. Mitchell has recently said that the physician who in cases where a certain moral mandate was to be impressed upon the patient has never sought the aid of the clergyman must have missed some valuable assistance. It may, perhaps, be assumed that reputable physicians will generally coincide with this judgment. But is this the best and all that you can do with Then I must tell you frankly that the clergy will never be satisfied with this meagre crumb falling from your bountiful table. And I will tell you why. We have a supernatural gift from God, our Maker and only Healer, and we "travail in birth" till that gift has been bestowed upon those committed to our care. Now, in saying this do not suppose that I purpose to engulf you in what has been described, with perhaps better judgment than wit, as "the delirious round of the Eddy." Besides, I entirely concur in the opinion of one of our most distinguished physicians that when a suggestion has to be made to a hypnotized subject it had better be made by a doctor than a priest.

But is it not true that large sections of the medical profession are restive under any suggestion of

the supernatural? If such is the case it would not be very surprising to me. They spend a large portion of their time and thought on the merely, exclusively physical. They compass land and sea that they may compel the earth to give up its treasures that in the laboratory and the mortar they may convert them into remedies for disease. They notice with care and exquisite nicety the products of chemical change, they observe and register with great accuracy the action of every modification of a drug. Their minds are continually occupied with one field of causes and results. Now, the mind forms habits as well as the body; and it is not hard for me to see, at least, that the custom of looking only at a particular class of phenomena and changes should gradually merge into the conviction that there were no others worthy of contemplation, if it did not go as far as to say that there were no others at all. As it has been strikingly put, their attention is so unfailingly fixed on second causes that they lose all sense and capacity for a first cause. But we ought to recognize this as a pitfall. The fact is that the very intelligence within us which leads us to look for and assign a cause compels us to affirm that behind all causes that we can trace there must have been One Who endowed them with potency. And, if my language seems hard to receive, this from an old Indian book, thousands of years before our era, perhaps, cannot be rejected: "How could that which is be born of that which is not?" I think you will agree with Max Müller: "The very question supplies the answer. It could not."

Now, under the guidance of this same most accomplished student of thought-and he is more useful to our purpose because he did not believe in supernatural religion—I should like to lead you on to ground where we both may stand firmly. He says: "That though the senses seem to deliver to us finite experiences only, many, if not all, of them can be shown to involve something beyond the known, something unknown, something which I claim the

liberty to call infinite:

"That in this way the human mind was led to the recognition of undefined, infinite agents or agencies beyond, behind, and within our finite experience;

"That the feelings of fear, awe, reverence, and love excited by the manifestation of some of these agents or powers began to react on the human mind, and thus produced what we call Natural Religion in its lowest and simplest form—fear, awe, reverence, and love of the gods." (Natural Religion,

pp. 105-6.)
"If," says this very able writer, "the psychological analysis of the earliest religious concepts as I had given it is correct—and no one, I believe, has denied the simple facts on which it rests-it follows that religion is a psychological necessity, and not, as Positivist philosophers maintain, a mere hallucination or a priestly fraud." (Ibid., 194.)

It will perhaps be felt that it is a far cry from this rudimentary position to the "things hard to be understood" in developed Christianity. And out of mercy to you I shall not this evening attempt to cover the distance. It is perhaps enough to say that if religion is necessary the best is none too

good for us.

With this in mind, then, let us quote from Dr. Dercum's very valuable paper. "The relief which patients experience by a full account of their symptoms, and the inevitable concomitant emotional discharge, is seen, in a more marked degree of course, and yet typically, in the making of confessions; at times the demand for relief under these circumstances is so great and so insistent that the sufferer voluntarily makes statements which he knows may lead to disgrace, imprisonment, and at times even to death." . . . "The therapeutic efficacy of their procedure Breuer and Freud explained as the catharsis of the repressed, 'locked up' emotion which had been attached to or associated with the suppressed psychic experience." (Therapeutic Ga-

zette, May 15, 1908.)

Under such conditions, which frequently occur in a physician's practice, what can he do? I assume that he always gives sympathy and, when possible, advice. Can he do more? Suppose we accept the fact that when Christ after His resurrection, in order to provide for all time for this most tragic want of the soul a remedy which would ensure peace as well as mere disclosure, said to His Apostles: "Peace be unto you; as My Father hath sent Me, even so send I you. And when He had said this He breathed on them and saith unto them, Receive ye the Holy Ghost: Whose soever sins ye remit, they are remitted unto them." And I need not call your attention to the number of instances where this gift, which, always the sovereign pre-rogative of God, was dispensed at His command through the agency of His representatives, always for the purpose which St. Paul in one instance pauses to state, "lest perhaps such an one should be swallowed up with overmuch sorrow . . . lest Satan get an advantage of us." For what is it, after all, that causes the terrible emotional upheaval which the physician sees in some instances to threaten reason itself, and compels confession? It is the sense of guilt, is it not? The awful shame at the recollection of the sinful act or habit and the knowledge that it deserves punishment. This God can remove, and he can restore the soul to snowy cleanness. And because many of us are so constituted that we obtain assurance that absolution has been passed upon us, only when he hear it from human lips, the Great High Priest when He was about to leave this earth authorized His underlings to speak the words in His name.

Suppose some one says I do not believe in this. I answer that as far as the psychotherapeutic value of the sacrament is concerned that makes no difference if the patient does. His restoration to health is what you aim to achieve. And the relief to his nervous tension is accomplished by his belief, not yours. And so on every ground it seems to be the wisdom of the physician to send such patients to

the priest or the priest to the patient.

I feel quite sure that most seriously minded physicians will not undervalue the psychiatric benefit of prayer. The reasons are so obvious as to be unnecessary to state. And this is the reason I suppose that we are told: "Is any sick among you? Let him call for the priests of the Church, and let them pray over him, anointing him with oil in the name of the Lord, and the prayer of faith shall save the sick and the Lord shall raise him up. There is also the Holy Communion, "The Body of our Lord Jesus Christ, which was given for you; preserve your body and soul unto everlasting life." I could from my own experience relate many remarkable instances of physical benefit resulting from all of these agencies. This does not seem germane to our present limited subject. I will ask the physicians, however, to believe the fact and give us priests the opportunity to contribute the gifts with which God has endowed us to assist and supplement those which He so efficiently administers for the bodies and souls of men through Please do not leave orders that we are to them. be excluded from the sick room. It may be that some priests have not every gift of delicacy and But might not the same be said of some physicians? I think you will find in all but exceptional cases, typhoid fever, for instance, all religious people physically benefited by our visits, and in a large percentage also of those whose spiritual life may gain its first serious impulse through the chastisement of illness, wisely directed by the expe-

rienced priest. I spoke at the outset of the grateful obligations of the priest to the physician which make it a pleasure for us to reflect upon and acknowledge. wonder if it is possible for us to reciprocate? the priest make any return to the physician? Of all professions, except my own, it would appear that that of the medical practitioner needed a life near to God more than any other. He is constantly in the presence of the mystery of pain. He can do much to relieve it; there is much of it that he cannot mitigate. He is in daily contact with death. Can he dismiss these things and go gayly to the next case? I think not. I know his tender heart is often racked by pain that passes from the sufferer into and sometimes through his soul. To be inspired then with a vivid realization that there was a great purpose in it all—that that nature which by sin had afflicted itself with disease, which issued in suffering and death, which by untold suffering even unto death had been redeemed by God, who enwrapped it within the folds of His Divinity that He might effect its purification, its restoration, must still in each individual bear its cross that he may share in the purity and health therein assured must buoy him up with hope and lend him courage

It does seem to me, my brethren, that every physician would indefinitely enlarge his sphere and increase the joy of his labors by taking unto himself the "truth as it is in Christ Jesus." Many a doctor has found the half hour in church in the early morning a source of strength for the labors of the day. And if the midday hours must be given to patients, there is still Even Song, with its sweet and lofty praise. There is the heart united to God in prayer and constantly lifted up to Him in the intervals, perhaps the perplexities, of a crowded and trying day.

to persevere.

It was, possibly, the special lines of study and the exigencies of a physician's life which led to those specific characteristics which discriminate the Third Gospel from each of the others, always recognized, but I think never expressed with greater charm than by the master of sacred poetry in the Middle Ages—Adam of St. Victor:

To Luke the ox belongs, for he, More clearly than the rest, doth see Christ as the Victim slain; Upon the Cross, as altar true, The bleeding, spotless Lamb we view, And see all else in vain.

IRON:

Metallic and Magnetic, Physical and Philosophical; Its Place in Mythology, in Demonology, in Astrology, in Medical and Surgical Therapeusis.

By JOHN KNOTT, A. M., M. D., Ch. B., and D. P. H. (Univ. Dub.); M. R. C. P. I.; M. R. I. A., Etc., Dublin, Ireland.

Solid, substantial, practical, and unobtrusive, iron approaches perhaps most nearly, in one direction, the reputation of fluid, slippery, weird, and uncanny mercury-in the possession of a specific power over the human organism which can be readily demonstrated in health, and may be beneficially utilized in the treatment of many of the most important varieties of disease. In this respect it also approaches more nearly the Valentinian reputation of antimony, and the Paracelsian one of sulphur, than does the all healing power so frequently claimed for gold in mediæval times, or the less comprehensive ones attributed to silver, or the wide range of curative effects discovered in the employment of the preparations of other metallic elements, as of the plumbic salts by the enthusiastic Goulard. The panaceal properties attributed to certain elements in those prescientific centuries had, very naturally, the effect of producing their tentative application in all types and varieties of disease. One good result at least was reached-pretty surely, indeed, after the loss (or sacrifice) of numberless constitutions and lives: The discovery of our most reliable (empiric) remedies. When all diseases, without exception, were due to either coagulation of the mercury or combustion of the sulphur (or effervescence of the salt) of the human economy, a desperate effort was made to replace the loss of the spoiled or missing element by introduction of a new supply from without. A very interesting specimen of the therapeutic information so obtained was supplied in the case of cutaneous disease. In those centuries when dirt was never removed from the integument, in accordance with the culture of the virtue of humility; and vermin were respectfully preserved, in accordance with the apostolic precept of mortification of the flesh; and syphilis was just quite new to Europe, at least the malignant contraband edition which had been directly imported from the West Indies, a very large proportion of the cases which exercised the skill and resources of the healer were those of skin And the results of the "experimental disease. method" above referred to led to a "practical" classification of skin diseases which obtained very wide currency in the seventeenth century, and can, I venture to suggest, be recommended to the best consideration of the practising therapeutist of the twentieth: 1, Those that mercury can cure; 2, those that sulphur can cure; and 3, those that the devil himself cannot cure. This last type was, of course, universally allowed to be that of most frequent occurrence!

The march of intellect has, since the date of this physical conception and rationalistic therapeusis of cutaneous diseases, made rapid and uninterrupted progress, "upwards and onwards." Chemical "elements" have increased in number to an extent unforeseen in those centuries in which the great central object of scientific pursuit was the agent by whose contact any one of the other (and altered) elements would be instantly transmuted (or rechanged) to the original and unique primitive type from which all had originally sprung. Indeed, they have increased so much in number, and, of recent years, with such rapidity, as to lead to the inevitable meeting of the extremes; the completion of the circular groove (or rut) of "progress," in which all inquisitive descendants of Eve seem condemned to move in their quest of the apple of knowledge. And the original conception of the taste of the "waters of bitterness" must have been impressed on many an intellect in the pilgrimage through the sandy soil of this desert of fact and theory (and experiment, and hypothesis, and discovery, and assertion)-true and false-on ascertaining that the scientific pioneer of the twentieth century is now stranded on the rock of the single "element" from which his ancestors sailed forth upon the boundless ocean of discovery some thousands of years ago! And in the ultimate arrangement of the constituent particles of the same, in the structure of the various items of the universe, he is left to choose between the Stoical continuum of Zeno and his disciples and followers) and the Epicurean finely grained alternation of plenum and inane (vacuum), which had been previously arranged by Moschus and Democritus, and has been so faithfully and skilfully embalmed for posterity in the inspired poetry of Lucretius.

The imperishable and indivisible atom of chemical theory and research may be said to have enjoyed a life career almost exactly conterminous with the existence of the nineteenth century. It came in with the infancy of that epoch, and displayed the significant symptoms of tottering debility with its decline. Few chemical or physical specialists were ever known, during that most vigorous age of scientific prosperity, to hint at the fact that their accepted "atomic theory" represented but an attempt to make the pre-Trojan hypothesis of Moschus to fit in with the ascertained facts of experimental "modernism." And the junior scientist who dared to give articulate utterance to the fact that no logical proof whatever was forthcoming of the existence of either atom or molecule, or could be produced by even the most inspired of contemporary doctrinaires, would, most assuredly, have been branded as a dangerous and irreclaimable heretic! The legal conditions of modern existence effectively forbade, of course, the application of the red hot iron for that purpose; but he would surely have been not the less effectively stamped with the indelible stigma of scientific insubordination, which would have permanently barred him out from a position from which he could conveniently disseminate his amateurish conceptions

among the adolescents of the coming chemical generation. Every intelligent schoolboy, even long before he began to "make up" the text of "the smaller Ganot," knew how to estimate with due scorn the prescientific idea of a large section of our philosophic ancestors, that "Nature abhors a vacuum." He even knew the recognized value of the childish notions of our remote classical predecessors in those fields of thought, who had taught their misguided disciples that the existing matter of the whole universe was arranged in four layers of concentric stratification: Earth, water, air, and fire; with a fifth something ('η πέμπτη οὐσία, quintessentia) everywhere permeating and universally animating the whole. Still more contemptible to the intellectual juvenility of the latter half of the past century was the cosmogony of the first of Greece's "wise men," who taught his contemporaries that all matter was the genetic resultant of the "permutations and combinations" of a single element - that of water (moisture).

He rarely, if ever, knew that the Mosaic chaos (of the Septuagint) represented the same idea; the familiar xãos of Greek philosophy having been derived, as Plutarch points out, from χέω (χέειν, to flow) and remained expressive of the special physical property of fluid movement. How few modernists seem to have grasped the fact of the unity of the original source of the currents of philosophic and inspired thought which travelled so slowly westward along the shores of the Mediterranean, from the seat of their primary genesis in the *Ur* (light, fire, generative heat) of the Chaldees. And probably-or say, if possible-fewer still recognize the identity of the Stoical teaching regarding the winding up of the existing zόσμος by universal diffusion of fire with that adopted by early Christianity, as shown in the text of the prophetic Revelation divinely vouchsafed to St. Peter (II Epist. iii, 12-13):

τής τού θεού ήμερας, εν ήν ούμανος πορουμενοι λυθήδονται και στοχεία καυσύμενα τήκεται. Καινούς δ' ούμανούς και γήν καινην κατά το επάγγελμα αύτου προσδοκώμεν —:

with the nineteenth century conception of Lord Kelvin that restless matter was everywhere settling down-with infinite varieties of velocity-into the (ashen and inanimate) sedimentary stage characterized by the universal attainment of the absolute zero temperature; and with the most recent (and, perhaps, the most ingenious) notion of Gustave le Bon; that all the atoms of our universe are continuously, if in degrees of various slowness, breaking up into the cosmic ether from which they were originally formed; that omnipresent medium which pervades all space-visible and invisible, tangible and intangible—and from which they were created. in the beginning, by the endowment of a special appropriate vortex motion! And so the universal cosmic vortex of Pythagoras shrank in due time into the more localized vortices of Descartes, and has now reached the ultramicroscopic dimensions of the vortical system of the individual atom! Below this dimensional level it can, assuredly, never hope to descend!

Thus our twentieth century philosopher who re-
